The regulation of rates has two aspects: control of the rate level and control of the rate structure. The rate level has to do with the size of a company's earnings. Here, the commission must seek to attain equity as between investors and consumers. The rate structure has to do with the particular rates paid by different classes of customers for different units of service. Here, the commission must seek to prevent treatment that is unduly discriminatory, favoring some customers and harming others.

**The rate level.** The general level of rates should be high enough, first, to cover the current costs of operation and, second, to yield an adequate return on the investment. Ideally, this return should be sufficient to be fair to past investors, avoiding impairment of the value of their property. It should also be high enough to preserve the credit standing of the regulated company so that it will be able to attract the capital needed if its service is to be improved and expanded.

Control of the rate level involves three different processes. First, it is necessary to control operating expenses. These expenses are usually the largest sum that must be covered in the rates. If they are inflated, the rates will be too high. Second, it is necessary to determine the rate of return on investment that is to be taken as fair to investors and as adequate for the maintenance of credit. This rate is expressed as a percentage of the value of the company's property. Third, it is necessary to determine the value of this property, estimating construction or reproduction costs and making due allowance for depreciation.

The commissions have not been vigorous in controlling operating expenses. In general, they have taken the view that decisions respecting the wisdom of expenditures lie within the province of management and have refused to substitute the judgment of regulators for that of managers. Accordingly, they have never sought the power to require that budgets be submitted for approval before money could be spent. The most that they do is to examine reports on expenses incurred in the past, and, if certain items seem improper, they may warn the companies concerned that they will not include such items in computing future rates. But regulation may be so lax that such warnings will have little effect.

**The rate base.** In determining the rate of return to be allowed on investments, the commissions operate within the limits of the constitution as it is interpreted by the courts. Under the fifth and fourteenth amendments to the constitution, federal and state governments, respectively, are

forbidden to deprive any person of property without due process of law. Applying this prohibition, the courts undertook, for many years, to review the rates that the commissions set. Their concern was to protect investors; their attention was focused, accordingly, upon the adequacy of earnings. Investors in regulated industries, they held, should be permitted a fair return upon a fair value of their investments. But the issues usually brought before them related not to the percentage adopted as a fair return but to the method used in determining fair value. Valuation of the rate base thus came to be the heart of the problem of controlling rates.

The points at issue in the valuation controversy had to do, in part, with the propriety of including intangible assets in the rate base and with the methods used in the treatment of depreciation. But these matters were overshadowed by the dispute between those who held that the properties should be evaluated on the basis of their original cost and those who would evaluate them on the basis of reproduction cost. With prices rising, reproduction cost would necessitate a higher level of earnings and of rates.

Beginning in 1898 the courts insisted that some weight be given to reproduction cost, rejecting a number of rate determinations on the ground that the weight accorded was insufficient. But they never stated what the proper weight would be, accepting a lower weight as adequate in one case and rejecting a higher weight as inadequate in another. As a result, rate determinations were held up by protracted litigation. The commissions, instead of taking formal action, sought to obtain such rate concessions as they could through informal negotiation. For nearly half a century the effectiveness of regulation was seriously impaired.

This situation was ended in 1944, when the Supreme Court declared that the method of valuation was to be left to the discretion of the commissions and that consideration, accordingly, need no longer be given to reproduction cost. Since that time, valuations made by the federal commissions and most of the state commissions have been based on original cost. Fair value, however, is still based on reproduction cost in a minority of states.

**The rate of return.** With settlement of the controversy over valuation, more importance has come to be attached to determination of a fair rate of return. Here, recognition has been given, first, to the fact that earnings need to be high enough to enable regulated companies to attract new capital. But no rules have been established for ascertaining the level of earnings required for this purpose. The nature of a company's capital structure, though

relevant, is not taken into account. The return required to ensure a market for common stocks is uncertain. Earnings can always be set at a level that will make such stocks attractive, but this may involve a larger return than is in fact required. Recognition is given, second, to the need for a return that will be fair to past investors. Here, the courts have said that earnings will be fair if they are equal to those obtainable in other industries with comparable risks. But this rule is rendered inoperable by the absence of industries with similar risks. The earnings needed to attract new capital, moreover, are likely to differ from those required for fairness to past investors. According to the one standard or the other, the return allowed will thus be too high or too low.

Other issues raised by the rate of return have been ignored. Earnings might well be averaged over time; they are calculated for a single year. Earnings might be adjusted to afford an incentive to efficiency; such adjustments have been made, but they are exceptions to the general rule. In practice, the commissions and the courts announce the percentages of return they hold to be fair, running from less than 6 per cent to as much as 8 per cent (or more in the case of airlines)—these figures varying from state to state, industry to industry, and year to year. But they do not disclose the considerations that have led to their decisions. The principles, if any, that govern the determination of a fair return are thus unknown.

*The level of transport rates.* In controlling utility earnings, fair return on fair value is still the rule, but, in the case of transport, this rule has long since been abandoned. Public utilities, in general, enjoy monopolies of essential services. Utility rates designed to yield a specified return can usually be relied upon to do so. Railroads, on the other hand, have always competed with one another. A fair return could not be separately fixed for each competitor but had to be established as an average for those in a competing group. Railroads have come to be faced, moreover, with the competition of other transport media. There is no assurance that a return adopted as fair for them will actually be obtained.

In 1920 Congress directed the ICC to set railway rates at a level that would enable the roads to earn an average return of  $5\frac{1}{2}$  per cent. This goal was never attained. In 1933 Congress enacted, in the Interstate Commerce Act, a new rule of rate making. The commission was now directed "to give due consideration . . . to the effect of rates on the movement of traffic; to the need . . . of adequate and efficient transportation service at

the lowest cost consistent with the furnishing of such service; and to the need of revenues sufficient to enable the carriers . . . to provide such service" (sec. 15a). The new rule made no mention of fair value. It called only for a return that would enable the railroads to attract new capital. Recognizing the existence of growing competition with increasing elasticity of demand, it acknowledged that the desired level of earnings in transport might not be attainable by raising rates. This rule was applied, within the next few years, not only to railroads but also to carriers by highway, by water, and by air.

*The rate structure.* Regulation is applied to the rate structure in order to control discrimination among consumers. The rates charged by transport and utility enterprises for various units of service are highly differentiated; railroads, for instance, charge different rates per ton-mile for carrying different commodities, or for the same commodity between different points; electric companies charge different rates for different uses and for different hours. These differences are to be explained, in part, by differences in cost. But they are also to be attributed, in large measure, to differences in demand. Where demand is elastic, rates are low; where it is inelastic, they are high.

Under certain circumstances there is a case to be made for discrimination. There must be idle capacity so that output can be increased. There must be high fixed charges so that cost per unit can be reduced as output grows. The added output must be salable only at the lower rates. These rates must be high enough to contribute to overhead. The general level of rates must be regulated to keep earnings reasonable and discrimination within bounds. Given these conditions, discrimination may result in lower prices for each class of customers and for each block of sales. It may bring about a fuller utilization of resources and a wider consumption of services.

Discrimination by regulated utility monopolies may thus have a generally beneficial effect. Discrimination by competing transport companies is unlikely to do so. The establishment of lower rates for goods that otherwise would not move at all may be of general benefit. But rates are also set lower on hauls where railroads compete for traffic and higher on hauls where they do not. Traffic that is attracted by the lower charges is diverted to one carrier from another. The one gets more revenue; the other gets less. With the former, unit costs are lowered; with the latter, they are raised. Shippers who use competing lines are benefited; those who use noncompeting lines are handi-

capped. It cannot be said that such discrimination is of benefit to the community as a whole.

*Regulation of the rate structure.* The law does not forbid discrimination as such but only that discrimination which may be held to be undue or unreasonable, giving one user of service an unfair competitive advantage and placing another under an unfair handicap. It is thus the function of the commissions to determine when discrimination is to be permitted and when forbidden. This work has taken a large part of the time of the ICC. It has been given little attention by the state utility commissions.

Initiative in setting individual rates is taken by the regulated companies, the commissions acting only in response to customer complaints. In the case of rail transport, such complaints have been numerous. In dealing with them over the years, the ICC has developed a body of precedent to which it adheres. In general the commission has sought to prevent discrimination among competing shippers. But it has also permitted discrimination where this was necessary to enable one carrier to compete with another for particular commodities and hauls. When the two principles have been in conflict, the latter has prevailed. The resulting structure of rates has been highly discriminatory.

The rate structure established by the utility companies has typically involved the use of classifications and differentials that have been based in part on differences in cost but in larger part on differences in the elasticity of demand. In the case of electricity, for instance, the low rates have gone to industry, where demand was elastic because it could produce its own power, and the high rates have been charged to householders, whose demand was inelastic because they could not. The commissions have accepted this pattern, subjected it to little scrutiny, and made little effort to have it modified.

*Regulation of utility monopolies.* In general, the regulation of utility monopolies has been lax. Control of service and the structure of rates has been minimal. Attention has been directed primarily to the rate level. But here, operating expenses have not really been controlled. The rate base, long inflated by reproduction-cost valuations, may now be tied to original cost. But the rate of return allowed is determined arbitrarily, without reference to stated criteria. Control of earnings is neither tight nor continuous. The earnings permitted have been well above those required to enable the utility companies to attract new capital. A rate case, moreover, may be brought as infre-

quently as once in a decade. In the meantime, if demand has grown and costs have declined, excessive profits have been realized and retained.

*Regulation of transport competition.* In the case of transport, regulation has come to have a different purpose and effect. Here, monopoly has given way to competition. It should have been possible, accordingly, to relax controls. Instead, they were intensified. It came to be the purpose of regulation not to protect shippers against monopolistic carriers but to protect competitive carriers against one another. The pattern of control developed for the railroads was extended to the other modes of transport. Control of entry and of rates came to be employed to make sure that each of these modes retained its accustomed share of the traffic. Entry into the trucking business was curtailed and routes were restricted. Emphasis in the control of rail rates shifted from the imposition of maxima to the imposition of minima. The railroads, in practicing discrimination, were permitted to meet the lower rates of other carriers but not to undercut them, even though still lower figures would have more than covered their out-of-pocket costs. As a result, the allocation of traffic came to be influenced less by the comparative economic advantages of the different transport media than by the regulations imposed by the ICC. It was not until 1958 that policy began to move in the direction of relaxing controls so that competition could be given somewhat freer play.

*Regulation of civil aviation.* Control of civil aviation is a case by itself. Here, safety regulation is in the hands of the Federal Aviation Agency and economic regulation in the hands of the Civil Aeronautics Board (CAB). It is with the latter that we are here concerned.

Air carriers, unlike surface carriers, derive their revenues predominantly from passengers. Until after World War II, airline revenues fell short of expenses and all the lines were subsidized. The government was concerned less with the regulation of fares than with determination of the subsidies. After the war, however, the trunk (long-haul passenger) lines gradually went off subsidy and the CAB undertook to develop a policy to govern regulation of the level of fares. Under this policy, as made public in 1960, the trunk lines are to be allowed a weighted average return of 10.5 per cent on their investment; the local feeder lines from 9 to 12.5 per cent depending upon the character of their capital structures, with 5.5 per cent allowed on their bonds and 21.35 per cent on their common stock. It is obvious that such rates of

return will not make for tight control of earnings. As for the structure of fares, no study has yet been made and no policy announced.

The CAB has maintained strict control over entry, permitting no new trunk lines to be established since it was created in 1938. It has encouraged the creation of local feeder lines, keeping them in existence by subsidization. Most of the board's time has been devoted to passing on applications for the right to fly particular routes. Here it has sought to ensure the existence of competitive services and, by granting added routes to weaker companies, to equalize the profitability of the airlines. The board has used its control of routes to stimulate the modernization of equipment and increase the frequency and speed of flights. At the same time, its control has delayed adaptation of routes to changing needs and has discouraged diversity in types of service. It may be questioned whether the resulting pattern of routes and complement of services is superior to those that would have obtained in the absence of regulation.

*Regulation of broadcasting.* In the case of radio and television, the Federal Communications Commission (FCC) is concerned primarily with the allocation of channels for broadcasting. Licenses conveying rights to exclusive use of channels, their value running into millions of dollars, are granted to broadcasters without charge. These grants are made on the basis of stated criteria. But the criteria are imprecise, subjective, inconsistent, and inoperable. They are given lip service but in practice are ignored. The real grounds for action are not disclosed. Commissioners have been subjected to improper pressures and have succumbed, in some cases, to bribery. Critics of the licensing process have proposed that licenses, instead of being given away, be auctioned off to the highest bidder. Such a change would put an end to the ambiguity and the temptation to corruption inherent in the present method of licensing. But, in itself, it would do nothing to improve the quality of programming.

It is here that regulation has failed most seriously. Its licensing power gives the FCC control over the structure of the industry, over contractual relations between the networks and their affiliated stations, and over progress in the adoption of new technology, but only nominal control over the character of programming. The commission has reserved a number of channels for educational broadcasting, authorized experimentation with pay television, and sought to curb the broadcasting of lotteries and of obscenity. But it has not revoked licenses or refused renewals on the ground that

the programs presented have failed to fulfill the broadcaster's promise to serve the public interest. Commission chairmen have admonished the industry from time to time to raise the general quality of their programs and to avoid the crasser abuses of advertising. But in the face of powerful political pressure, the commission has lacked the courage to order them to do so.

*Shortcomings of regulation.* There are a few regulatory commissions that have consistently maintained a record of vigorous action in the public interest and a few that have taken such action upon occasion. But, by and large, the agencies have fallen short of the performance they had promised. They have not anticipated changing conditions or developed broad policies to guide control but have waited for cases to be brought before them, permitting policy to emerge from the processes of adjudication. They have not sped decisions through informal action but have delayed them by adhering to cumbersome procedures. They have not fulfilled their promise of independence and impartiality. The commissions are dependent on the executive for appointments, for budget requests, and for political support; on the legislature for jurisdiction, for powers, for confirmation of appointments, and for appropriations. Lacking insulation from political pressures, they have been unable to take an independent line.

More than this, the commissions have come increasingly to serve the interests of the industries they were set up to regulate. When first established, through popular demand for reform, they had the support of the executive and the legislature and thus were able to embark with some zeal upon their regulatory duties. In time, however, public attention has shifted to other problems. Executives have made poor appointments and have failed to provide political backing. Legislatures have denied adequate jurisdiction, powers, and appropriations. The commissions, lacking any other clientele, have turned to the regulated industries for support. Working day in and day out with industry officials, they have become immersed in industry's problems and have come to share its point of view. The consumer's interest has been lost from sight.

*Inherent limitations of regulation.* The commissions' powers could be strengthened, their personnel improved, and their appropriations increased. But there are limitations inherent in the pattern of regulation that such reforms could not remove. Regulation cannot itself prescribe quality, force efficiency, or require innovation; to do so, it would have to duplicate the central functions of

management. Nor does it offer a reward for good performance or impose a penalty for poor performance in these respects. On the contrary, rate regulation involves cost-plus pricing. If management is diligent in cutting costs, rates will be reduced; if it is indolent, they will be increased. If regulation were tight there would be no incentive to efficiency or to progress. If such an incentive does, in fact, exist, it is because regulation is lax.

Regulation could conceivably prevent monopolistic enterprises from charging monopoly prices and obtaining monopoly profits. But it does not attempt to maximize consumption by setting rates at the lowest level that will yield a fair return. Regulation is backward-looking. The necessary level of rates is computed by multiplying price per unit by past demand. Elasticity of demand is not taken into account. The possibility that lower charges might be justified by growth of demand or by innovations in technology is ignored. As a result, the level of rates, even if monopoly profits are excluded, is higher than it needs to be.

Regulation is inevitably slow. It must satisfy the requirements of due process: investigate, give notice, hold hearings, study the record, make findings, issue orders, permit appeals. All this takes time and delays action. In some cases, delay may be harmful, as when it permits earnings to rise well above or to fall far below the return required to attract new capital. In other cases, it may be helpful, as when it brakes an inflationary spiral of wages and prices. But here, the merit of regulation lies not in its efficiency but in its inefficiency.

Regulatory agencies tend to become industry-minded, seeking to protect the regulated industry against low rates and impaired earnings. This orientation makes, too, for regulation-mindedness. Where effectiveness of the regulator's controls is weakened by the freedom of firms beyond his jurisdiction, he seeks wider jurisdiction. Where the applicability of his controls is lessened by changing circumstances, he seeks tighter controls. Thus, in transport, where monopoly has given way to competition, the original purpose of regulation might have been better served if jurisdiction had been narrowed or controls relaxed. But policy, over the years, has favored expansion of coverage and elaboration of detail.

The regulated industry comes, in the end, to have two masters: its own management and the regulatory agency. Managerial decisions are reviewed. Where the regulatory agency finds them to be wise, it allows them to stand. Where it finds them to be unwise, it exercises a veto power. Negotiation between the managers and the regula-

tors takes time; decisions are inevitably delayed. Division of authority diverts energy from the solution of external problems to the prosecution of internal disputes. At the same time, it dissipates responsibility.

The ICC is required, for instance, to consider the probable effect of the rates it sets upon the volume of traffic. In doing so, it may substitute its own judgment for that of railway managements. If earnings fall, there is no one whom the owners of the roads can hold responsible. The managements are deprived of power; the commission has power but lacks responsibility. Even if managements are not reversed, decisions may be so delayed that substantial losses are sustained. In cases such as this, the management escapes responsibility by blaming the regulators. But the regulators cannot be held accountable.

#### REICH, WILHELM

Wilhelm Reich was born in 1897, in what was the Austrian part of Poland, and died in 1957 in Lewisburg, Pennsylvania. He was a psychoanalyst and social philosopher, originating one of the dissi-

dent trends of thought derived from Freudian psychoanalysis. His early contributions to the clinical field are accorded general esteem, while his later ideas (which encompass virtually all the sciences from physics to psychology), his social philosophy, and his attempts to translate this philosophy into large-scale social action are generally considered grandiose, the products of a passion that gradually gave way to schizophrenic deterioration.

Reich became a dissident from Freudian orthodoxy by following Freud's original path to its logical end, as he saw it. His productive thought took off from two of Freud's early hypotheses. The first maintains the existence of a type of neurosis (*Aktualneurose*) caused by an actual physiological disturbance of sexuality. According to this view, frustrated excitement, coitus interruptus, etc., can independently of any mental factors produce this kind of neurosis. Although Freud himself continued to consider the hypothesis correct, he did not pursue this trend of thought once he became involved in the investigation of psychological conflicts. The second hypothesis maintains that the characteristics of a person's sexuality determine the characteristics of his personality. This is an oversimplification that Freud implicitly withdrew when he hypothesized the ego as an entity to be studied in its own right.

Reich extended Freud's hypothesis of the *Aktualneurose*. He held that not only the *Aktualneurose* but also the psychoneuroses are characterized, indeed caused, by a damming up of undischarged and, in this state, noxious sexual energy. The dissipation of noxious sexual energy is the irreplaceable function of the orgasm. Extending Freud's hypothesis that sexuality determines personality, Reich declared that psychic health depends upon orgasmic potency. The orgasmically potent individual is free of destructive aggression and will spontaneously, without the pressure of a moral conscience, enjoy doing what is right and socially beneficial (1927, vol. 1).

The goal of psychoanalytic therapy for Reich, therefore, is to free the orgasmic function of the neurotic. Reich became convinced that in order to achieve this goal, psychoanalytic therapists must above all attack the patient's resistances rather than interpret unconscious contents, as they typically did at that time. Taking a productively fresh and wide view of character resistances, he perceived them not only in symptoms, inhibitions and anxieties, attitudes and values, but also in such less obvious guises as habits, mannerisms, and particularly muscular tensions. These last he came to regard as materialization of the "character armor,"

which function to prevent the outbreak of neurotic anxiety caused by the undischarged sexual tensions (1933-1935).

If the neuroses are maintained by the "muscular armor," then a direct attack may be made on them by melting down the "armor." This can be done by encouraging a patient to relax strategic groups of muscles. The analyst then has to assist the patient in the assimilation and mastery of emotions presumably thus liberated. Reich designated such treatment "vegetotherapy" and for a while thought that it provided him with a simple technique for the sexual liberation of individuals (1933-1935).

But by the late 1920s his interest had already gone beyond therapy merely for individuals. He sought—and believed he had found—a theory that justified large-scale social action. As a radical interpreter of the early Freud he had no doubt that suppression of the sexual impulses in children and adolescents is responsible for the high incidence of neurosis. This suppression he saw as bound up with the institution of the authoritarian family, on which the entire authoritarian structure of society in turn depended. Reich hoped he could destroy authoritarianism both in the family and in society at large by encouraging the young victims of the system to revolt and to win sexual freedom (1932). He attempted in vain to gain acceptance for these views, first in the socialist, then in the communist parties of Europe, and finally founded his own organization to propagate them.

Eventually Reich's interests took a different direction. He believed he had discovered the physical reality corresponding to "psychic energy." He called it "orgone" (1927) and claimed that the surface of the healthy human body radiated this form of energy, whereas bodies of the neurotics and those suffering from a great variety of other illnesses, including cancer, were deficient in it. In the United States, where he lived from 1939 until his death, he constructed and sold "orgone boxes" and recommended them for cancer therapy. Patients seated in them presumably absorbed life-enhancing rays, which the boxes gathered from the surrounding abundance of orgone in the universe. An agency of the U.S. government, ignorant of Reich's background and assuming his orgone to be simple commercial quackery, eventually caused him to be sent to prison, where he died of a heart attack.

During his years in America, Reich was followed and supported by devoted believers, including physicians, laymen, and artists. At the time of this writing, 1965, the Reich cult seems to be in decline but not extinguished.

- I. ANTHROPOLOGICAL STUDY
- II. THE SOCIOLOGY OF RELIGION
- III. PSYCHOLOGICAL STUDY

Clifford Geertz  
Robert N. Bellah  
James E. Dittes

#### I

#### ANTHROPOLOGICAL STUDY

The anthropological study of religion has been highly sensitive to changes in the general intellectual and moral climate of the day; at the same time, it has been a powerful factor in the creation of that climate. Since the early discussion by Edward Tylor, interest in the beliefs and rituals of distant, ancient, or simpler peoples has been shaped by an awareness of contemporary issues. The questions that anthropologists have pursued among exotic religions have arisen from the workings—or the misworkings—of modern Western society, and particularly from its restless quest for self-discovery. In turn, their findings have profoundly affected the course that quest has taken and the perspective at which it has arrived.

Perhaps the chief reason for the rather special role of comparative religious studies is that issues which, when raised within the context of Western culture, led to extreme social resistance and personal turmoil could be freely and even comfortably handled in terms of bizarre, presumably primitive, and thus—also presumably—fanciful materials from long ago or far away. The study of “primitive religions” could pass as the study of superstition, supposedly unrelated to the serious religious and moral concerns of advanced civilization, at best either a sort of vague foreshadowing of them or a grotesque parody upon them. This made it possible to approach all sorts of touchy subjects, such as polytheism, value relativism, possession, and faith healing, from a frank and detached point of view. One could ask searching questions about the historicity of myth among Polynesians; when asked in relation to Christianity, these same questions were, until quite recently, deeply threatening. One could discuss the projection of erotic wishes found in the “totemic” rites of Australian aborigines, the social roots and functions of African “ancestor worship,” or the protoscientific quality of Melanesian “magical thought,” without involving oneself in polemical debate and emotional distress. The application of the comparative method—the essence of anthropological thought—to religion per-

mitted the growth of a resolutely scientific approach to the spiritual dimensions of human life.

Through the thin disguise of comparative method the revolutionary implications of the work of such men as Tylor, Durkheim, Robertson Smith, Freud, Malinowski, and Radcliffe-Brown soon became apparent—at first mainly to philosophers, theologians, and literary figures, but eventually to the educated public in general. The meticulous descriptions of tribal curiosities such as soul loss, shamanism, circumcision, blood sacrifice, sorcery, tree burial, garden magic, symbolic cannibalism, and animal worship have been caught up in some of the grander intellectual battles of the last hundred years—from those over evolutionism and historicism in the late nineteenth century to those over positivism and existentialism today. Psychoanalysts and phenomenologists, Marxists and Kantians, racists and egalitarians, absolutists and relativists, empiricists and rationalists, believers and skeptics have all had recourse to the record—partial, inconsistent, and shot through with simple error as it is—of the spiritual life of tribal peoples to support their positions and belabor those of their opponents. If interest in “primitive religion” among savants of all sorts has been remarkably high, consensus concerning its nature and significance has not.

At least three major intellectual developments have exercised a critical influence on the anthropological study of religion: (1) the emergence, in the latter half of the nineteenth century, of history as the sovereign science of man; (2) the positivist reaction against this sovereignty in the first decades of the twentieth century and the radical split of the social sciences into resolutely psychological approaches, on the one hand, and resolutely sociological ones, on the other; and (3) the growth, in the interwar period, of a concern with the role of ideational factors in the regulation of social life. With the first of these came an emphasis on the nature of primitive reasoning and the stages of its evolution into civilized thought. With the second came an investigation of the emotional basis of religious ritual and belief and the separate examination of the role of ritual and belief in social integration. The concern with value systems and other features of the ideational realm led to an exploration of the philosophical dimensions of religious ideas, particularly the symbolic vehicles in terms of which those ideas are expressed.

### Evolutionism and its enemies

Like so much else in anthropology, the study of the religious notions of primitive peoples arose

within the context of evolutionary theory. In the nineteenth century, to think systematically about human affairs was to think historically—to seek out survivals of the most elementary forms and to trace the steps by which these forms subsequently developed. And though, in fact, Tylor, Morgan, Frazer, and the rest drew more on the synthetic social-stage theories of such men as Comte and Hegel than on the analytic random-variation and natural-selection ideas of Darwin, the grand concept of evolution was shared by both streams of thought: namely, that the complex, heterogeneous present has arisen, more or less gradually, out of a simpler, more uniform past. The relics of this past are still to be found scattered, like Galápagos turtles, in out-of-the-way places around us. Tylor, an armchair scholar, made no “voyage of the *Beagle*.” But in combing and organizing the reports of missionaries, soldiers, and explorers, he proceeded from the same general premise as did Darwin, and indeed most of the leading minds of the day. For them a comprehensive, historically-oriented comparison of all forms of a phenomenon, from the most primitive to the most advanced, was the royal road to understanding the nature of the phenomenon itself.

In Tylor's view, the elementary form out of which all else developed was spirit worship—*animism*. The minimal definition of religion was “a belief in spiritual beings.” The understanding of religion thus came down to an understanding of the basis upon which such a belief arose at its most primitive level. Tylor's theory was intellectualistic. Belief in spirits began as an uncritical but nonetheless rational effort to explain such puzzling empirical phenomena as death, dreams, and possession. The notion of a separable soul rendered these phenomena intelligible in terms of soul departure, soul wandering, and soul invasion. Tylor believed that the idea of a soul was used to explain more and more remote and hitherto inexplicable natural occurrences, until virtually every tree and rock was haunted by some sort of gossamer presence. The higher, more developed forms of “belief in spiritual beings,” first polytheism, ultimately monotheism, were founded upon this animistic basis, the ur-philosophy of all mankind, and were refined through a process of critical questioning by more advanced thinkers. For this earnest Quaker the religious history of the world was a history of progressive, even inevitable, enlightenment. [See TYLOR.]

This intellectualistic, “up from darkness” strain has run through most evolutionist thought about religion. For Frazer, a nineteenth-century figure who lived for forty years into the twentieth century

without finding it necessary to alter either his views or his methods, the mental progress involved was from magic to religion to science. Magic was the primordial form of human thought; it consisted in mistaking either spatiotemporal connection ("sympathetic magic," as when drinking the blood of an ox transfers its strength to the drinker) or phenomenal similarity ("imitative magic," as when the sound of drumming induces thunderheads to form) for true scientific causality. For Durkheim, evolutionary advance consisted in the emergence of specific, analytic, *profane* ideas about "cause" or "category" or "relationship" from diffuse, global, *sacred* images. These "collective representations," as he called them, of the social order and its moral force included such sacra as "mana," "totem," and "god." For Max Weber, the process was one of "rationalization": the progressive organization of religious concern into certain more precisely defined, more specifically focused, and more systematically conceived cultural forms. The level of sophistication of such theories (and, hence, their present relevance) varies very widely. But, like Tylor's, they all conceive of the evolution of religion as a process of cultural differentiation: the diffuse, all-embracing, but rather unsystematic and uncritical religious practices of primitive peoples are transformed into the more specifically focused, more regularized, less comprehensively authoritative practices of the more advanced civilizations. Weber, in whom both intellectualism and optimism were rather severely tempered by a chronic apprehensiveness, called this transformation the "disenchantment (*Entzauberung*) of the world." [See DURKHEIM; FRAZER; WEBER, MAX.]

On the heels of evolutionism came, of course, antievolutionism. This took two quite different forms. On one side there was a defense, mainly by Roman Catholic scholars, of the so-called degradation theory. According to this theory, the original revelation of a high god to primitive peoples was later corrupted by human frailty into the idol worship of present-day tribal peoples. On the other side there was an attack, mainly by American scholars of the Boas school, upon the "armchair speculation" of evolutionary thinkers and a call for its replacement by more phenomenological approaches to the study of tribal custom.

The first of these reactions led, logically enough, to a search among the most primitive of existing peoples for traces of belief in a supreme being. The resulting dispute, protracted, often bitter, and stubbornly inconclusive as to the existence of such "primitive monotheism," turned out to be unproductive—aside from some interesting discussions by

Lang (1898) concerning culture heroes and by Eliade (1949) concerning sky gods—and both the issue and the theory that gave rise to it have now receded from the center of scholarly attention. The second reaction has had a longer life and great impact on ethnographic methodology, but it too is now in partial eclipse. Its main contributions—aside from some devastating empirical demolitions of evolutionist generalization—came in the field of cultural diffusion. Leslie Spier's study of the spread of the Sun Dance through the Great Plains (1921) and A. L. Kroeber's application of the age-area approach to aboriginal religion in California are good examples of productive diffusion studies. However, apart from their importance for culture history, the contribution of such distributional studies to our understanding of religious ideas, attitudes, and practices as such has not been great, and few students now pursue these studies. The call of the Boas school for thorough field research and disciplined inductive analysis has been heeded; but its fruits, insofar as religious studies are concerned, have been reaped by others less inhibited theoretically.

### Psychological approaches

The major reaction against the intellectual tradition of the cultural evolutionists took place not within anthropology, however, but in the general context of the positivist revolt against the domination of historicist modes of thought in the social sciences. In the years before World War I the rise of the systematic psychologism of psychoanalysis and of the equally systematic sociologism of the *Année sociologique* forced evolutionist theorizing into the background, even though the leaders of both movements—Freud and Durkheim—were themselves still very strongly influenced by it. Perhaps even more relevant, it introduced a sharp split into anthropological studies of religion which has resolved into the militantly psychodynamic and the militantly social-structural approaches.

Freud's major work in this field is, of course, *Totem and Taboo*, a book anthropologists in general have had great difficulty in evaluating—as Kroeber's two reviews of it, the first facetiously negative, the second, two decades later, ambivalently positive, demonstrate. The source of the difficulty has been an inability or an unwillingness to disentangle Freud's basic thesis—that religious rituals and beliefs are homologous with neurotic symptoms—from the chimerical ethnology and obsolete biology within which he insisted upon setting it. Thus, the easy demolition of what Kroeber called Freud's "just so story" concerning primal incest,

parricide, and guilt within some protohuman horde ("in the beginning was the deed") was all too often mistaken for total rejection of the rather more penetrating proposition that the obsessions, dreams, and fantasies of collective life spring from the same intrapsychic sources as do those of the isolated individual.

For those who read further in Freud's writings, however—especially in "Mourning and Melancholia" and "Obsessive Acts and Religious Practices"—it became apparent that what was at issue was the applicability of theories concerning the forms and causes of individual psychopathology to the explanation of the forms and causes of public myth and group ritual. Róheim (1950) analyzed Australian circumcision rites against the background of orthodox Freudian theories of psychosexual development, especially those clustered around the Oedipal predicament. However, he explicitly avoided recourse to speculations about buried memories of primordial occurrences. Bettelheim (1954) adopted a similar, though more systematic and less orthodox, approach to initiation practices generally, seeing them as socially instituted symbolic mechanisms for the definition and stabilization of sexual identity. Kardiner (1945), taking a neo-Freudian position, sought to demonstrate that the religious institutions of tribal peoples were projections of a "basic personality structure," formed not by the action of an unconsciously remembered historical trauma but by the more observable traumas produced by child-training practices, an approach later extended and cast into quantitative form by Whiting (Whiting & Child 1953). Erikson (1950), drawing upon developments in ego psychology which conceived the emergence of the adult personality to be a joint product of psychobiological maturation, cultural context, and historical experience, interpreted the religious notions of the Yurok and the Sioux in terms of certain basic modes of relating to the world. These relationships gradually developed during the whole course of childhood and adolescence. Others—notably Devereux (1951)—have attempted to use the autobiographical, case-history approach to determine the relations between personality dynamics and religious orientation in particular individuals; still others—notably Hallowell (1937–1954)—have employed projective tests, questionnaires, reports of dreams, or systematic interviews toward similar ends.

In all such studies, even when individual authors have dissented from many of Freud's specific views, the basic premise has been Freudian: that religious practices can be usefully interpreted as expressions

of unconscious psychological forces—and this has become, amid much polemic, an established tradition of inquiry. In recent years, however, responsible work of this type has come to question the degree to which one is justified in subjecting historically created and socially institutionalized cultural forms to a system of analysis founded on the treatment of the mental illnesses of individuals. For this reason, the future of this approach depends perhaps more upon developments within psychoanalysis, now in a somewhat uncertain state, than within anthropology. So far, perhaps only Kluckhohn's pioneering *Navaho Witchcraft* (1944) has attempted to systematically relate psychological factors to social and cultural aspects of primitive religion. The great majority of psychoanalytic studies of tribal beliefs and rites remain willfully parochial.

In any case, not all psychological approaches to religion have been Freudian. Jungian influences have had a certain impact, especially on studies of myth. Campbell (1949), for example, has stressed the continuity of certain themes both cross-culturally and temporally. These themes have been interpreted as expressions of transpersonal constancies in unconscious mental functioning which are at the same time expressions of fundamental cosmic realities.

Simple emotionalist theories have also been extremely popular. There have been two main varieties of these: awe theories and confidence theories. Awe theories have been based on some usually rather vague notion of "religious thrill" experienced by human beings when brought face to face with cosmic forces. A wide range of ethnologists, from Max Müller through Lang and Marett to Lowie and Goldenweiser, have accepted such theories in one form or another. However, awe theories remain mere notations of the obvious—that religious experience is, in the nature of the case, touched with intense feelings of the grandeur of the universe in relation to the self and of the vulnerability of the self in relation to the universe. This is not explanation, but circular reasoning.

Confidence theories also begin with a notion of man's inward sense of weakness, and especially of his fears—of disease, of death, of ill fortune of all kinds—and they see religious practices as designed to quiet such fears, either by explaining them away, as in doctrines of the afterlife, or by claiming to link the individual to external sources of strength, as in prayer. The best-known confidence theory was that set forth by Malinowski. He regarded magic as enabling man to pursue uncertain but essential endeavors by assuring him of

their ultimate success. Confidence, or anxiety-reduction, theories, like awe theories, clearly have empirical foundation but do not adequately explore the complex relationship between fear and religious activity. They are not rooted in any systematic conceptualization of mental functioning and so merely point to matters desperately in need of clarification, without in fact clarifying them.

### Sociological approaches

The sociological approach to the analysis of the religions of nonliterate peoples proceeded independent of, and even at variance with, the psychoanalytic approach, but it shared a concern with the same phenomenon: the peculiar "otherness," the extraordinary, momentous, "set apart" quality of sacred (or "taboo") acts and objects, as contrasted with the profane. The intense aura of high seriousness was traced by Freud to the projection of unacceptable wishes repressed from consciousness onto external objects. The dramatic ambivalence of the sacred—its paradoxical unification of the commanded and the forbidden, the pure and the polluted, the salutary and the dangerous—was a symbolic expression of the underlying ambivalence of human desires. For Durkheim too the extraordinary atmosphere surrounding sacred acts and objects was symbolic of a hidden reality but a social, not a psychological one: the moral force of the human community.

Durkheim believed that the integrity of the social order was the primary requisite for human survival and the means by which that integrity superseded individual egocentricity was the primary problem of sociological analysis. He saw Australian totemism, which he like Freud made the empirical basis of his work, as a mechanism to this end. For example, the collective rituals involving the emblems of the totemic beings—the so-called *totem feasts*—aroused the heightened emotions of mass behavior and evoked a deep sense of moral identification among the participants. The creation of social solidarity was the result of the creation of public veneration by specific groups of persons of certain carefully designated symbolic objects. These objects had no intrinsic value except as perceptible representations of the social identity of the individuals. Collective worship of consecrated trees of painted wood or stone created a *social community*, a "church," upon which rested the vitality of the major social units. These sanctified objects thus represented the system of rights and obligations implicit in the social order and the individuals' unfettered sense of its overriding significance in his life. All sacred objects, beliefs,

and acts, and the extraordinary emotions attending them, were outward expressions of inward social necessities, and, in a famous phrase, God was the "symbol of society." Few anthropologists have been able to swallow Durkheim's thesis whole, when put this baldly. But the more moderate proposition that religious rituals and beliefs both reflect and act to support the moral framework underlying social arrangements (and are in turn animated by it) has given rise to what has become perhaps the most popular form of analysis in the anthropological study of religion. Usually called "functionalism"—or sometimes, to distinguish it from certain variants deemed objectionable, "structuralism"—this approach found its champion in Radcliffe-Brown and its major development in Great Britain, though its influence has now spread very much more widely.

Radcliffe-Brown (1952) agreed with Durkheim's postulate that the main role (or "function") of religion was to celebrate and sustain the norms upon which the integration of society depends. But, unlike Durkheim (and like Freud), Radcliffe-Brown was concerned with the content of sacred symbols, and particularly with the reasons why one object rather than another was absorbed into rite or woven into myth. Why here stones, there water holes, here camp circles, there personified winds?

Durkheim had held this to be an arbitrary matter, contingent upon historical accident or psychological proclivity, beyond the reach of and irrelevant to sociological analysis. Radcliffe-Brown considered, however, that man's need for a concrete expression of social solidarity was not sufficient explanation of the structure of a people's religious system. Something was needed to tie the particular objects awarded sacred status (or, in his terminology, "ritual value") to the particular social interests they presumably served and reflected. Radcliffe-Brown, resolute empiricist that he was, chose a solution Durkheim had already magisterially demolished—the utilitarian. The objects selected for religious veneration by a given people were either directly or indirectly connected to factors critical to their collective well-being. Things that had real, that is, practical, "social value" were elevated to having spiritual, or symbolic, "ritual value," thus fusing the social and the natural into one overarching order. For primitives at least (and Radcliffe-Brown attempted to establish his theory with regard to the sanctified turtles and palm leaves of the preagricultural Andaman Islanders and, later on, with regard to Australian totemism), there is no discontinuity, no difference even, between moral and physical, spiritual and practical relationships

and processes. These people regard both men and things as parts of a single normative system. Within that system those elements which are critical to its effective functioning (or, sometimes, phenomena empirically associated with such elements, such as the Andaman cicada cycle and the shifting monsoons) are made the objects of that special sort of respect and attention which we call religious but which the people themselves regard as merely prudential.

Radcliffe-Brown focused upon the content of sacred symbols and emphasized the relation between conceptions of the moral order of existence and conceptions of its natural order. However, the claim that the sanctity of religious objects derives from their practical social importance is one of those theories which works when it works and doesn't when it doesn't. Not only has it proved impossible to find even an indirect practical significance in most of the enormous variety of things tribal peoples have regarded as sacred (certain Australian tribes worship vomit), but the view that religious concerns are mere ritualizations of real-life concerns leaves the phenomenon of sacredness itself—its aura of mystery, power, fascination—totally unexplained.

More recent structuralist studies have tended to evade both these questions and to concentrate on the role played by religion in maintaining social equilibrium. They attempt to show how given sets of religious practices (ancestor worship, animal sacrifice, witchcraft and sorcery, regeneration rites) do in fact express and reinforce the moral values underlying crucial processes (lineage segmentation, marriage, conflict adjudication, political succession) in the particular society under investigation. Arnold van Gennep's study of crisis rites was perhaps the most important forerunner of the many analyses of this type. Although valuable in their own right as ethnography and as sociology, these structural formulations have been severely limited by their rigid avoidance, on the one side, of the kind of psychological considerations that could account for the peculiar emotions which permeate religious belief and practice, and, on the other, of the philosophical considerations that could render their equally peculiar content intelligible. [See GENNEP.]

### The analysis of symbolic forms

In contrast to other approaches—evolutionary, psychological, sociological—the field of what we may loosely call “semantic studies” of religion is extremely jumbled. There is, as yet, no well-established central trend of analysis, no central

figure around whom to order debate, and no readily apparent system of interconnections relating the various competing trends to one another.

Perhaps the most straightforward strategy—certainly the most disarming—is merely to accept the myriad expressions of the sacred in primitive societies, to consider them as actual ingressions of the divine into the world, and to trace the forms these expressions have taken across the earth and through time. The result would be a sort of natural history of revelation, whose aim would be to isolate the major classes of religious phenomena considered as authentic manifestations of the sacred—what Eliade, the chief proponent of this approach, calls hierophanies—and to trace the rise, dominance, decline, and disappearance of these classes within the changing contexts of human life. The meaning of religious activity, the burden of its content, is discovered through a meticulous, wholly inductive investigation of the natural modalities of such behavior (sun worship, water symbolism, fertility cults, renewal myths, etc.) and of the vicissitudes these modalities undergo when projected, like the Son of God himself, into the flux of history.

Metaphysical questions (here uncommonly obtrusive) aside, the weaknesses of this approach derive from the same source as its strengths: a drastic limiting of the interpretations of religion to the sort that a resolutely Baconian methodology can produce. On the one hand, this approach has led, especially in the case of a scholar as erudite and indefatigable as Eliade, to the uncovering of some highly suggestive clusterings of certain religious patterns with particular historical conditions—for example, the frequent association of sun worship, activist conceptions of divine power, cultic veneration of deified heroes, elitist doctrines of political sovereignty, and imperialist ideologies of national expansion. But, on the other hand, it has placed beyond the range of scientific analysis everything but the history and morphology of the phenomenal forms of religious expression. The study of tribal beliefs and practices is reduced to a kind of cultural paleontology whose sole aim is the reconstruction, from scattered and corrupted fragments, of the “mental universe of archaic man.”

**Primitive thought.** Other scholars who are interested in the meaningful content of primitive religion but who are incapable of so thoroughgoing a suspension of disbelief as Eliade, or are repelled by the cultic overtones of this somewhat mystagogic line of thought, have directed their attention instead toward logical and epistemological considerations. This has produced a long series of studies

that view "primitive thought" as a distinctive mode of reasoning and/or a special body of knowledge. From Lévy-Bruhl through Lévi-Strauss, and with important contributions from members of the evolutionary, psychoanalytic, and sociological schools as well, this line of exploration has persisted as a minor theme in anthropological studies of religion. With the recent advances in linguistics, information theory, the analysis of cognition, semantic philosophy, modern logic, and certain sorts of literary investigation, the systematic study of symbolic activity bids fair to become, in a rather thoroughly revised form, the major theme for investigation. The "new key" Susanne K. Langer heard being struck in philosophy in the early 1940s—"the concern with the concept of meaning in all its forms"—has, like the historicist and positivist "keys" before it, begun to have its echo in the anthropological study of religion. Anthropologists are increasingly interested in ideational expression, increasingly concerned with the vehicles, processes, and practical applications of human conceptualization.

The development of this approach has come in two fairly distinct phases, one before and one after World War II. In the first phase there was a concern with "the mind of primitive man" and in particular with its capacity for rational thought. In a sense, this concern represented the evolutionists' interest in primitive reasoning processes detached from the historicist context. In the second phase, which is still in process, there has been a move away from, and in part a reaction against, the subjectivist emphasis of the earlier work. Ideational expression is thought of as a public activity, rather like speech, and the structure of the symbolic materials, the "language," in whose terms the activity is conducted becomes the subject of investigation.

The first, subjectivist, phase was animated by a protracted wrangle between those who used the religious beliefs and practices of tribal peoples as evidence to prove that there was a qualitative difference between the thought processes of primitives and those of civilized men and the anthropologists who considered such religious activity as evidence for the lack of any such differences. The great protagonist of the first school was the French philosopher Lévy-Bruhl, whose theories of "prelogical mentality" were as controversial within anthropology as they were popular outside it. According to Lévy-Bruhl, the thought of primitives, as reflected in their religious ideas, is not governed by the immanent laws of Aristotelian logical reasoning, but by affectivity—by the vagrant flow of emotion and the dialectical principles of "mystical

participation" and "mystical exclusion." [See LÉVY-BRUHL.]

The two most effective antagonists of Lévy-Bruhl's theories concerning primitive religion were Radin and Malinowski. Radin, influenced by Boas' more general attacks on theories of "primitive mentality," sought to demonstrate that primitive religious thought reaches, on occasion, very high levels of logical articulation and philosophical sophistication and that tribal society contains, alongside the common run of unreflective doers ("men of action"), contemplative intellectuals ("men of thought") of boldness, subtlety, and originality. Malinowski attacked the problem on an even broader front. Using his ethnographic knowledge of the Trobriand Islanders, Malinowski argued that alongside their religious and magical notions (which he, too, regarded as mainly emotionally determined) the "savages" also had a rather well developed and, as far as it went, accurate empirical knowledge of gardening, navigation, housebuilding, canoe construction, and other useful arts. He further claimed that they were absolutely clear as to the distinction between these two sorts of reasoning, between mystical-magical and empirical-pragmatic thinking, and never confused them in actual practice. Of these two arguments, the former seems to be today nearly universally accepted and was perhaps never in fact really questioned. But with respect to the latter, serious doubts have arisen concerning whether the lines between "science," "magic," and "religion" are as simple and clear-cut in the minds of tribal peoples (or any peoples) as Malinowski, never one for shaded judgments, portrayed them. Nevertheless, between them, Radin and Malinowski rather definitively demolished the notion of a radical qualitative gap between the thought processes of primitive and civilized men. Indeed, toward the end of his life even Lévy-Bruhl admitted that his arguments had been badly cast and might better have been phrased in terms of different modes of thinking common to all men. (In fact, Freud, with his contrast between primary and secondary thinking processes, had already made this distinction.) [See MALINOWSKI; RADIN.]

Thus, the debate about what does or does not go on in the heads of savages exhausted itself in generalities, and recent writers have turned to a concern with the symbolic forms, the conceptual resources, in terms of which primitives (and non-primitives) think. The major figure in this work has been Claude Lévi-Strauss, although this line of attack dates back to Durkheim and Mauss's influential 1903 essay in sociological Kantianism, *Primitive Classification*. The writings of E. E.

Evans-Pritchard on Zande witchcraft, Benjamin Whorf on Hopi semantics, and Gregory Bateson on Iatmul ritual and, among nonanthropologists, works by Granet, Cassirer, and Piaget have directed attention to the study of symbolic formulation.

**Symbolic systems.** Lévi-Strauss, whose rather highly wrought work is still very much in progress, is concerned with the systems of classification, the "homemade" taxonomies, employed by tribal peoples to order the objects and events of their world (see Lévi-Strauss 1958; 1962). In this, he follows in the footsteps of Durkheim and Mauss. But rather than looking, as they did, to social forms for the origins and explanations of such categorical systems, he looks to the symbolic structures in terms of which they are formulated, expressed, and applied. Myth and, in a slightly different way, rite are systems of signs that fix and organize abstract conceptual relationships in terms of concrete images and thus make speculative thought possible. They permit the construction of a "science of the concrete"—the intellectual comprehension of the sensible world in terms of sensible phenomena—which is no less rational, no less logical, no more affect-driven than the abstract science of the modern world. The objects rendered sacred are selected not because of their utilitarian qualities, nor because they are projections of repressed emotions, nor yet because they reflect the moral force of social organization ritualistically impressed upon the mind. Rather, they are selected because they permit the embodiment of general ideas in terms of the immediately perceptible realities—the turtles, trees, springs, and caves—of everyday experience; not, as Lévi-Strauss says, apropos of Radcliffe-Brown's view of totems, because they are "good to eat," but because they are "good to think."

This "goodness" exists inherently in sacred objects because they provide the raw materials for analogical reasoning. The relationships perceived among certain classes of natural objects or events can be analogized, taken as models of relationships—physical, social, psychological, or moral—obtaining between persons, groups, or other natural objects and events. Thus, for example, the natural distinctions perceived among totemic beings, their species differentiation, can serve as a conceptual framework for the comprehension, expression, and communication of social distinctions among exogamous clans—their structural differentiation. Thus, the sharp contrast between the wet and dry seasons (and the radical zoological and botanical changes associated with it) in certain regions of Australia is employed in the mythology of the native peoples. They have woven an elaborate origin myth around

this natural phenomenon, one that involves a rain-making python who drowned some incestuous sisters and their children because the women polluted his water hole with menstrual blood. This model expresses and economizes the contrasts between moral purity and impurity, maleness and femaleness, social superiority and inferiority, fertilizing agent (rain) and that which is fertilized (land), and even the distinction between "high" (initiate) and "low" (noninitiate) levels of cultural achievement.

Lévi-Strauss contends that primitive religious systems are, like all symbolic systems, fundamentally communications systems. They are carriers of information in the technical Shannon-Weaver sense, and as such, the theory of information can be applied to them with the same validity as when applied to any physical systems, mechanical or biological, in which the transfer of information plays a central regulative role. Primitives, as all men, are quintessentially multichanneled emitters and receivers of messages. It is merely in the nature of the code they employ—one resting on analogies between "natural" and "cultural" distinctions and relationships—that they differ from ourselves. Where there is a distinguishing difference, it lies in the technically specialized codes of modern abstract thought, in which semantic properties are radically and deliberately severed from physical ones. Religion, primitive or modern, can be understood only as an integrated system of thought, logically sound, epistemologically valid, and as flourishing in France as in Tahiti.

It is far too early to evaluate Lévi-Strauss's work with any assurance. It is frankly incomplete and explorative, and some parts of it (the celebration of information theory, for example) are wholly programmatic. But in focusing on symbol systems as conceptual models of social or other sorts of reality, he has clearly introduced into the anthropology of religion a line of inquiry which, having already become common in modern thought generally, can hardly fail to be productive when applied to tribal myth and ritual.

Whether his own particular formulation of this approach will prove to be the most enduring remains, however, rather more of a question. His rejection of emotional considerations and his neglect of normative or social factors in favor of an extreme intellectualism which cerebralizes religion and tends to reduce it yet again to a kind of undeveloped (or, as he puts it, "undomesticated") science are questionable. His nearly exclusive stress on those intellectual processes involved in classification, i.e., on taxonomic modes of thought (a

reflex of his equally great reliance on totemic ideas as type cases of primitive beliefs), at the expense of other, perhaps more common, and certainly more powerful styles of reasoning, is also doubtful. His conception of the critical process of symbolic formulation itself remains almost entirely undeveloped—hardly more than a sort of associationism dressed up with some concepts from modern linguistics. Partly as a result of this weakness and partly as a result of a tendency to consider symbol systems as entities functioning independently of the contextual factor, many of his specific interpretations of particular myths and rites seem as strained, arbitrary, and oversystematized as those of the most undisciplined psychoanalyst.

But, for all this, Lévi-Strauss has without doubt opened a vast territory for research and begun to explore it with theoretical brilliance and profound scholarship. And he is not alone. As the recent work of such diverse students as Evans-Pritchard, R. G. Lienhardt, W. E. H. Stanner, Victor W. Turner, Germaine Dieterlen, Meyer Fortes, Edmund R. Leach, Charles O. Frake, Rodney Needham, and Susanne K. Langer demonstrates, the analysis of symbolic forms is becoming a major tradition in the study of primitive religion—in fact, of religion in general. Each of these writers has a somewhat different approach. But all seem to share the conviction that an attempt must be made to approach primitive religions for what they are: systems of ideas about the ultimate shape and substance of reality.

Whatever else religion does, it relates a view of the ultimate nature of reality to a set of ideas of how man is well advised, even obligated, to live. Religion tunes human actions to a view of the cosmic order and projects images of cosmic order onto the plane of human existence. In religious belief and practice a people's style of life, what Clyde Kluckhohn called their *design for living*, is rendered intellectually reasonable; it is shown to represent a way of life ideally adapted to the world "as it really" ('fundamentally,' 'ultimately') is." At the same time, the supposed basic structure of reality is rendered emotionally convincing because it is presented as an actual state of affairs uniquely accommodated to such a way of life and permitting it to flourish. Thus do received beliefs, essentially metaphysical, and established norms, essentially moral, confirm and support one another.

It is this mutual confirmation that religious symbols express and celebrate and that any scientific analysis of religion must somehow contrive to explain and clarify. In the development of such an analysis historical, psychological, sociological, and

what has been called here semantic considerations are all necessary, but none is sufficient. A mature theory of religion will consist of an integration of them all into a conceptual system whose exact form remains to be discovered.

#### II

#### THE SOCIOLOGY OF RELIGION

Sociologists have undertaken three main types of religious study. They have studied religion as a central theoretical problem in the understanding of social action. They have studied the relation between religion and other areas of social life, such as economics, politics, and social class. And finally,

they have studied religious roles, organizations, and movements. This article will be concerned primarily with the theoretical study of religion and secondarily with the relation between religion and the social structure.

### Historical background

The sociological study of religion has grown out of and remains inextricably related to the much broader effort to understand the phenomenon of religion that has been made by scholars in many fields, especially since the eighteenth century in the West and more recently in other parts of the world. Theologians, philosophers, historians, philologists, literary critics, political scientists, anthropologists, and psychologists have all made contributions. In untangling this immensely complicated story it will be helpful to resort to a simplified schema that focuses on two main lines of intellectual development: the "rationalist" and the "nonrationalist" traditions. (A writer is referred to here as "nonrationalist" not because his thought is considered to be irrational but because he takes the nonrational aspect of human existence as central and irreducible.) Both traditions have roots deep in the history of Western thought and analogues in the thought of some non-Western cultures. The eighteenth century saw a certain crystallization of both traditions, which had important consequences for the nineteenth century and which still affects us in many respects.

**The rationalists and nonrationalists.** The rationalist tradition, which was closely associated with the rise of secular thought and skepticism in England and France in the seventeenth and eighteenth centuries, later stimulated the nonrationalist tendency as a reaction to it. Of course, the rationalists themselves were partly grappling with the great seventeenth-century antirationalist Blaise Pascal. It was the position of the rationalists that the apparently nonrational could not only be brought within the bounds of rational analysis but also could be eliminated as an influence on human action, though most of them doubted that this would ever be possible for the masses. Thus, they held that the obviously absurd doctrines of established religion had come into existence because of ignorance and the deliberate chicanery of the priests, who were serving their own self-interest as well as that of the secular despots who were often their masters. Behind the absurd historical forms, the deists discerned a natural religion in accordance with the dictates of reason.

Rousseau and Kant were transitional figures. Both believed in a generalized "reasonable" religion

in preference to any historical faith, but they grounded their religious convictions on human nature (Rousseau) or the dictates of ethical experience (Kant) rather than on purely cognitive arguments. The nonrationalist tradition, which subsequently developed mainly in Germany, emphasized the *sui generis* quality of religion. Johann Gottfried Herder held that religion was grounded in specific experience and feeling rather than in reason. In the early nineteenth century Friedrich Schleiermacher undertook the first systematic exposition of this position. He held that religion was to be understood neither as crude philosophy nor as primitive ethics but rather as a reality in its own right; it is grounded neither in knowledge nor in action but in feeling. More specifically, he came to think that religion derives fundamentally from the feeling of absolute dependence. Both Herder and Schleiermacher, rejecting as they did a rationalist understanding of religion, opposed the search for a universal natural religion of self-evident reasonableness. Rather, they insisted on taking seriously the particular forms of culture and religion in all their historical diversity. Herder was, of course, one of the most important forerunners of nineteenth-century historicism, and Schleiermacher was one of the first to develop the tools of cultural interpretation (hermeneutics), which provided the main methodological equipment of the movement in Germany.

While the nonrationalist treatment of religion in Germany was closely related to the development of idealist philosophy there, the rationalist treatment of it was closely related to the rise of positivism in France and utilitarianism in England during the nineteenth century. Historicism cut across these distinctions and came to dominate Anglo-French as well as German thought. In both France and England rationalism in its historicist phase took the form of evolutionism.

Comte's famous theory of the three stages viewed theology as appropriate in the childhood of man; however, it was to be displaced first by philosophy and then by science as men's rational understanding of the universe gradually increased. Comte interpreted religion in terms that we would now call "functional," stressing the contribution of belief and ritual to social solidarity and the control of personal feelings. While thus recognizing nonrational factors in religion and, indeed, arguing from them that religion is a permanent and inescapable aspect of human existence, he nonetheless stressed cognitive factors almost exclusively in his theory of religious evolution.

In England, Spencer developed an evolutionary

perspective on religion that was even more narrowly cognitive than Comte's, and Tylor also undertook an extensive effort to understand the religious development of mankind in these terms. In treating the development from animism through polytheism to monotheism as a succession of more and more adequate cognitive hypotheses, he remained thoroughly in the rationalist tradition. Frazer, while formally maintaining the same point of view, embraced a range of material—ritual kingship, human sacrifice, fertility ritual, and the like—which actually demanded a different interpretation. His *Golden Bough* (1890) can be viewed as a marvelously intuitive catalogue of central problems that would have to be solved by other means. Finally, in the English tradition, Marett's discussion (1900) of mana and preanimism came very near breaking through the preconceptions of the rationalist utilitarian school.

Dilthey, who was a follower of Schleiermacher as well as a neo-Kantian, continued the German nonrationalist tradition by stressing the irreducible nature of the religious *Weltanschauung* and the necessity for an inner understanding (*Verstehen*) of its particular forms. This tradition led directly into the modern sociological study of religion through the work of Troeltsch and particularly that of Max Weber, who both transcended the tradition in important respects. Postponing a consideration of these men for a moment, we may trace further into the twentieth century the development of the German tradition that was relatively independent of the influence of Weber and Troeltsch. A certain formal culmination was reached in the work of Rudolph Otto. In his important book *The Idea of the Holy* (1917), he richly developed the basic intuition of Schleiermacher by spelling out the phenomenology of the holy in terms of the numinous—the notion of the *mysterium tremendum et fascinosum*. Here more clearly than ever was the assertion of the *sui generis* nature of religion and its "geometrical location" in a certain kind of immediate experience. That experience, according to Otto, can be phenomenologically understood, but it cannot be explained. This point was made quite explicit in the work of van der Leeuw, who shared Otto's essential position: in the preface to *Religion in Essence and Manifestation* van der Leeuw said that he specifically disavowed all "theories" ([1933] 1938, p. vi). Thus Otto and the later exponents of this tradition—whether they were phenomenologists (such as van der Leeuw and Mircea Eliade) or were specifically interested in the sociology of

religion (Joachim Wach and Gustav Mensching)—have given us a rich array of materials without appreciably advancing our theoretical understanding.

Generalizing the argument so far, we may say that while the nonrationalist tradition jealously guarded the specific nature of religion but eschewed any explanation of it, the rationalist tradition provided a number of ways of explaining religion which in the end explained it away. We will argue, following Talcott Parsons' *The Structure of Social Action* (1937), that around the turn of the twentieth century several men from both traditions broke free of their preconceptions and converged on a more adequate approach to religion (and indeed to social phenomena generally).

However, just as we have noted that the non-rationalist tradition continues to our own day in relatively pure form, so we must point out that the utilitarian rationalist position also continues, not so much as a conscious tradition of scholarship as a semiconscious preconception of scholars in many fields. This preconception has been strengthened by its gradual fusion with a Marxian understanding of religion as essentially an ideological cover, either for the defense of the social status quo or for protests against it. Here religion is treated as a weapon in the political-economic struggle or as a preliminary stage in a political movement, a stage that may be outgrown with the attainment of political maturity. What is at issue is not the empirical adequacy of such analyses in particular instances, but rather the generalization of them as adequate for the understanding of the phenomenon of religion.

**Foundations of an adequate theory.** The architects of a more adequate understanding of religion were Durkheim, Weber, and Freud, though others also made important contributions.

**Contributions of Weber and Durkheim.** Weber maintained the idea of the centrality and irreducibility of nonrational elements in human action as it had developed in the German tradition, but he was not content with a mere phenomenological description of these elements. According to Parsons' analysis, Weber began, at least incipiently, to place these nonrational elements within the context of a general theory of social action. This he did through two of his central concerns. The first was with the problems of *meaning*—of evil, suffering, death, and the like—which are inescapable in human life but insoluble in purely scientific terms. Weber argued that the alternative religious answers to these problems of meaning

have had not only profound consequences for the motivation of individuals but also, in the long run, important causal effects on social development. The second of Weber's concerns, which links irrational elements to a more general theory of action, was with what he called *charisma*. Charisma is primarily a quality of the individual that places him above normal expectations and endows him with the authority to utter new commandments. Charisma is a relational concept—that is, it comes into existence only when it is recognized by a group. It links deeper levels of psychic organization, within the charismatic individual and in the members of the group who recognize him, with the social process and particularly with the possibility of radical discontinuities in social development. In both cases Weber was arguing for the importance of religion in social action on the grounds of its closeness to powerful nonrational motivational forces and its capacity to give form and pattern to those forces, including its capacity to create radically new forms and patterns.

The rationalist positivist tradition was decisively broken through from within by Durkheim, when he recognized that religion is a reality *sui generis*. By this he meant that religious representations or symbols are not delusions, nor do they simply stand for some other phenomena, such as natural forces or (contrary to some interpretations of his work) social morphology. Rather, in his social Kantianism, he held that religious representations are constitutive of society. They exist within the minds of individuals so as to inhibit egocentric impulses and to discipline the individual so that he can deal objectively with external reality. These shared representations, with their capacity to direct and control personal motivation, are what make society possible. While his treatment of motivation remained rudimentary, he did point out very clearly the great importance of religious action for stimulating individuals to participate positively in social life (see the discussion of collective effervescence in Durkheim 1912, book 2, chapter 7) and for dealing with tendencies of individuals to withdraw from social life (see the discussion of funeral ritual in 1912, book 3, chapter 5).

Although they started from opposite directions, both Weber and Durkheim seem to have overcome the impasse in which the rationalist and non-rationalist approaches to religion had long been caught: they both placed religion in a theoretical rather than a purely descriptive context, without denying its centrality and irreducibility. However,

they lacked any fine-grained structural understanding of the nonrational elements involved, even though they recognized their importance. It was in the work of Freud that a structural understanding of the relevant emotional and motivational elements was to be found for the first time.

*Freud's work on religious symbolism.* Freud's early work on the stages of psychosexual development was applied to religion in *Totem and Taboo* (1913), where the Oedipus complex with its mixture of dependence, love, and hostility was seen as the core problem of religious symbolism, which he treated as largely projective. Freud's later ego psychology, heralded in the important essays "Group Psychology and the Analysis of the Ego" (1921) and "The Ego and the Id" (1923), provided the basis for a much more active understanding of religious symbolism, which could now be treated not merely as reflecting psychic conflict but as actually affecting the outcome of psychic conflict and redirecting psychic forces. This point of view was applied to religion in the somewhat idiosyncratic but extraordinarily fruitful *Moses and Monotheism* (1934–1938). "The Future of an Illusion" (1927) represents a reversion to the early projective theory of religion and is neither the final statement of Freud's position nor even typical of his own late thinking.

By the early 1920s, then, the elements of a more adequate theory of religion had come into existence. However, at just this point the primary preoccupation with religion displayed by most of the great social scientists of the late nineteenth and early twentieth centuries disappeared. Other issues occupied the center of attention. Even today a theoretical concern with religion is only gradually reviving as a central issue in social science.

### A theory of religion

Only in the last few years has a new model of human action developed that will allow us to utilize the insights of Weber, Durkheim, and Freud without falling back into the old controversies about idealism and materialism, rationalism and irrationalism, and humanism and science. This is the cybernetic model (for a relevant, though partial, exposition, see Deutsch 1963). Parsons' action theory is the chief link between earlier social science and cybernetic theory and has itself in recent years been increasingly restated in cybernetic terms. This model, whose basic terms are "energy" and "information," seems likely to integrate the range of behavioral research

that stretches from the work of biologists such as Nikolaas Tinbergen and J. P. Scott on animal behavior to that of philosophers such as Ernst Cassirer and Susanne K. Langer on symbolic forms.

**The cybernetic model.** An action system may be defined as the symbolically controlled, systematically organized behavior of one or more biological organisms. The energy of such a system is supplied by the organism and is organized through genetically controlled organic structures that are not directly open to symbolic influence. Thus the basic motivation of the action system—its drives and needs—is partially determined by organic structure, although it is subject, through learning processes, to a considerable degree of symbolic control. The precise boundary, or, perhaps better, the area of overlap, between what is genetically and what is symbolically controlled is by no means clear, and important research on the problem is continuing. For present purposes it is only necessary to note the relatively broad plasticity for symbolic learning that is usually recognized, at least in the human species.

Information in such a system consists largely of symbolic messages that indicate something about either the internal state or the external situation of the action system. These messages are understood or interpreted by matching them with previously learned symbolic patterns, which make up the memory of the system. New situations can be understood through a recombination of previously learned elements, so that a new symbolic pattern is created. Thus, the set of symbolic patterns existing in a system will be partially determined by the nature of the external world with which that system has had to deal and by the nature of the laws governing the cognitive processes of the brain. Within these limits there is a wide range of freedom, within which alternative symbolic patterns may operate with equal or nearly equal effectiveness, as is best illustrated perhaps in the phenomenon of language.

The cybernetic model thus conceives of a human action system as autonomous, purposive, and capable of a wide range of external adaptations and internal rearrangements within the very broad constraints inherent in the nature of energy and information. It is precisely the stress on autonomy, learning capacity, decision, and control that gives the cybernetic model the ability, lacking in previous mechanistic and organic models, to assimilate the contributions of the humanistic disciplines—the *Geisteswissenschaften*—without abandoning

an essentially scientific approach [see *SYSTEMS ANALYSIS, articles on SOCIAL SYSTEMS and POLITICAL SYSTEMS*].

The openness of an action system is always relative to its particular structure. We have noted that energy is structured by genetic information from the organism and by symbolic information from the culture. Energy and information are further structured by two systems that can be seen as integrating organic motivation and symbols: personality and society. These are symbolically patterned motivational systems; the first centers on individual organisms, and the other on groups. Any particular personality or social system will be determined in large part at any given moment by its history, for its learning capacity will be largely a product of the structures it has built up over time. However, if a system has managed to develop a broad and flexible capacity for rapid learning, and if it has a reserve of uncommitted resources, its reaction to any given internal or external situation will be open to a wide variety of alternative choices; in other words, it will have a high degree of freedom.

**The role of religion in action systems.** Religion emerges in action systems with respect to two main problems. In order to function effectively, it is essential that a person or group have a relatively condensed, and therefore highly general, definition of its environment and itself. Such a definition of the system and the world to which it is related (in more than a transient sense) is a conception of *identity*. Such a conception is particularly necessary in situations of stress and disturbance, because it can provide the most general set of instructions as to how the system is to maintain itself and repair any damage sustained.

In addition to the identity problem, there is the problem of dealing with inputs of motivation from within the system that are not under the immediate control of conscious decision processes. We have already noted that such motivation is partly under the control of genetic rather than symbolic processes. In addition, as Freud discovered, there are important symbolically organized systems of motivation that are partially blocked or screened off from consciousness through the mechanism of repression; this happens partly as a result of the pattern of child raising. Though these unconscious motivational forces exist in individuals, they are to a large degree shared in groups, because human biology and child-raising patterns are, broadly speaking, similar. The emotions can be seen as signaling devices by which the conscious decision

process (the ego, in Freud's terms) becomes aware of the existence of important inputs of motivation from unconscious levels of the system.

The problems of identity and of unconscious motivation are closely related, for it is just those situations of threat, uncertainty, and breakdown, which raise the identity issue, that also rouse deep unconscious feelings of anxiety, hope, and fear. An identity conception capable of dealing with such a situation must not only be cognitively adequate but must also be motivationally meaningful. It is precisely the role of religion in action systems to provide such a cognitively and motivationally meaningful identity conception or set of identity symbols. It is such a set of symbols that provides answers to Weber's problems of meaning and to which Durkheim referred in speaking of religious representations. It is also what in large part Freud meant when he spoke of the superego. This mode of analysis leads to a definition of religion very close to that of Clifford Geertz, who wrote: "A religion is a system of symbols which acts to establish powerful, pervasive and long-lasting moods and motivations in men by formulating conceptions of a general order of existence and clothing these conceptions with such an aura of factuality that the moods and motivations seem uniquely realistic" (1966, p. 4).

The conception of religion briefly sketched here—religion as the most general mechanism for integrating meaning and motivation in action systems—applies to all types of action systems, not only to whole societies or groups of them. Many smaller units (individual personalities and groups) appropriate the religious symbols of their social and cultural environment in dealing with their own religious problems, though always with some degree of individual variation. Moreover, even where prevailing religious symbol systems are rejected, the idiosyncratic solutions of individuals and groups to fundamental problems of orientation and identity may be viewed in terms of this scheme as "religious." Of course, the degree to which religious problems will be salient for any individual or group is quite variable.

#### Current theoretically relevant research

While the theory outlined above has not previously been stated in exactly these terms, some recent research seems to be guided by a conception of religion as a control system linking meaning and motivation—a conception that is a close parallel of this theory. Three particularly interesting examples of such research will be cited. Each of

them concentrates at a traditional level of social science—psychological, social, or cultural—but it is noteworthy that they all transcend the discipline boundaries in trying to understand religion.

**Analysis of historical figures.** The first is the application of detailed psychological analysis to significant figures in religious history. Erik H. Erikson, in *Young Man Luther* (1958), has overcome a tendency toward psychological reductionism that was evident in some earlier work of this sort. He is careful to place Luther's life history in its proper social, historical, and religious context. In doing so, he shows how Luther was able to solve his own problem of identity, which had its roots deep in his unconscious conflicts, through constructive innovation with respect to religious symbolism. However, Erikson's knowledge of the deep motivational forces involved does not lead him to deny the contribution of the religious reformulation itself. Rather, he emphasizes the fusing and forming power of the symbols to synthesize motivational conflicts and control destructive impulses.

Erikson also contributes to the broader problem of religious change by indicating that Luther's solution, once it was embodied in communicable symbolic form, could be appropriated by others in the same society who had analogous identity problems arising from social-historical matrices similar to Luther's own. Moreover, although the argument is not worked out in detail, Erikson implies that Luther was able to contribute to certain social and cultural identity problems of Germany in particular and of Western civilization in general. This detailed analysis of the mechanism involved in a major example of religious change, although it involves only one among several types of change, is an important contribution to one of our least understood problems. [See **IDENTITY, PSYCHO-SOCIAL.**]

**Small-group research.** The second new line of research has to do with the analysis of religious phenomena in small groups, as illustrated in Philip E. Slater's *Microcosm* (1966). The small-group situation provides a laboratory within which the symbolic processes involved in group formation, as hypothesized by Durkheim and Freud, can be empirically synthesized. Slater shows how the group and its leader become foci for the unconscious anxieties, hopes, and fears of the members in the initial situation of uncertainty and lack of definition. These feelings are handled initially by the development of projective symbols, which are redolent with the mysterious potency of the unconscious feelings, that is, are highly magical and

sacred. However, over time, as more and more of the group process becomes consciously understood and as the deeper feelings about the group and the leader are worked through, the group itself becomes "secularized" and the quality of the sacred is relegated to certain group ideals and symbols of group solidarity.

Slater's comparison of this process of group development with the long-term process of religious evolution is highly suggestive. Particularly important is the perception of the changing role of symbolism with respect to the meaning-motivation balance as the group itself undergoes new experiences and changes in structure. Also of great general significance is Slater's observation that social and psychological aspects of group process interpenetrate at every point and that a purely psychological or a purely sociological theoretical framework would result in an inadequate understanding of the processes at work.

**Analysis of language as symbolic action.** A third area of promising research is the analysis of language as symbolic action as it has been developed by Kenneth Burke in his *Rhetoric of Religion* (1961) and other works. Burke's theory of artistic form (defined as "the arousing and fulfilling of expectations"), which is based on the Aristotelian theory of catharsis, emphasizes the working through of emotional tensions in symbolic form; thus, it is very close to the theory of religion developed above. Burke has pointed out that the tensions may be social as well as psychological, though they must be presented in personal terms if they are to have emotional impact. He has also pointed out the function of social and psychological control that such symbolic working through performs.

Perhaps Burke's chief contribution is his insistence on the special formal qualities of language and symbolism generally. Language does not merely reflect or communicate social and psychological realities. Rather, language contains within itself a "principle of perfection" (1961, epilogue), which operates relatively independently of other factors. That is, a terminology, once established, has certain "entelechia" implications. For example, once the terms *king*, *society*, and *god* come into existence, there is the logical possibility that someone will ask what a perfect king, society, or god is and from this analysis actually draw conclusions about existing kings, societies, or ideas of god. Regardless of the many actual social and psychological blocks to carrying through such analyses, the fact is that the possibility of pushing toward terminological perfection is always

present, and under certain circumstances it will actually be pursued. This is one of the chief reasons why cultural symbol systems cannot be treated entirely reductionistically. In *The Rhetoric of Religion* Burke has applied these insights with great brilliance to two key religious documents: the first three chapters of Genesis and Augustine's *Confessions* [see INTERACTION, article on DRAMATISM].

### Religion and society

An interest in the social consequences of religious belief and action is probably as old as the interest in religion itself. In the sixteenth century Machiavelli gave, in his *Discourses*, a functional analysis of Roman religion which had considerable influence. Spinoza, Montesquieu, Rousseau, and Comte continued and developed the analysis of the political significance of religious commitment and the related problems of the influence of religion on personal morality and social solidarity. In one of the earliest quantitative studies in sociology, Durkheim introduced a "religious variable" in his study of suicide (1897). Subsequently many studies of varying breadth and quality have included a religious variable and thus advanced our knowledge of the influence or lack of influence of religion on some aspect of social existence; however, a comprehensive survey of the results obtained is still lacking.

The man who contributed most to the systematic understanding of the interrelations between religion and society and who stimulated more research (both quantitative and nonquantitative) than any other scholar was undoubtedly Max Weber. The most influential single hypothesis in this field is certainly his thesis on the influence of the Protestant ethic on the rise of modern society (1904-1905). Although the cumulated argument and evidence on this thesis are too massive to review here, one recent study by Gerhard Lenski (1961) is worth mentioning, not only because it sheds light on the Protestant-ethic thesis in contemporary America but also because it is perhaps the most successful attempt to apply the methods of survey research to the sociology of religion. Lenski was concerned with the influence of religious affiliations and beliefs on attitudes toward work, authority, education, and a variety of other matters in a large American city, and he found this influence to be considerable. Weber's ideas on the non-Western religions have been applied much more sporadically (see the incomplete review in Bellah 1963), but as the comparative horizon of the sociology of religion widens, these

ideas seem likely to attract more attention. In this same connection, a revival of interest in religious evolution as providing the soundest classificatory system for comparative work can also be expected.

### Religious evolution

Although foreshadowings of the idea of religious evolution can be traced as far back as classical times, the first extensive effort in this direction was that of Vico in the eighteenth century. Elaborate schemes of religious evolution with copious empirical illustration were developed in the nineteenth century by Hegel, Comte, and Spencer. In more modest and judicious form, evolutionary ideas provided the basis of the sociology of religion of Durkheim (1912) and Weber (1922). Though long neglected and in some quarters excoriated, the idea of religious evolution has recently been revived (Bellah 1964). It provides the natural link between the kind of theory of religion sketched in this article and the comparative study of religion.

If one defines religion as a control system linking meaning and motivation by providing an individual or a group with the most general model that it has of itself and its world, then it becomes apparent that such a control system can vary in degree of complexity in ways that are not entirely random with respect to the degree of complexity of the social system of which it is a part. Since it has been clear for a long time that levels of social and cultural complexity are best understood in an evolutionary framework, it seems inevitable that religion too must be considered in such a framework.

Here it is possible only to enumerate some of the most important dimensions along which religious evolution can be expected to occur. The central focus of religious evolution is the religious symbol system itself. Here the main line of development is from compact to differentiated symbolism, that is, from a situation in which world, self, and society are seen to involve the immediate expression of occult powers to one in which the exercise of religious influence is seen to be more indirect and "rational." This is the process of the "disenchantment of the world" that was described by Weber. Part of this process is the gradual differentiation of art, science, and other cultural systems as separate from religious symbolism. Furthermore, changes in the nature and position of religious symbolism effect changes in the conception of the religious actor. The more differentiated symbol systems make a greater demand on the individual for decision and commitment.

To support this growing religious individualism, specifically religious group structures are required, whereas at earlier stages religion tends to be a dimension of all social groups. Finally, the capacity for religion to provide ideals and models for new lines of social development increases with the growing symbolic, individual, and social differentiation.

An adequate theory of religious evolution would have to go hand in hand with a general theory of social evolution. For example, the varying saliency of law, custom, and religion as agencies of social control in different societies, which was long ago pointed out by Montesquieu, could probably best be explicated by a general analysis of the evolution of control systems. Moreover, the contribution that a theory of religious evolution could make to a general conception of social evolution is also considerable. Such an approach would begin to indicate the ways in which changes in social structure impinge on the integration of established cultural meanings with the deeper levels of individual personalities and how shifts in that meaning-motivation balance can in turn help or hinder social differentiation.

### III PSYCHOLOGICAL STUDY

Religion affords dramatic, insistent phenomena centrally entrenched in the intimate structures and functions of personality. These phenomena are likely to intrigue a psychologist for one of two contrasting reasons: either for their challenging uniqueness or for their vivid illustration of factors of more fundamental and general interest in psychology.

Sometimes, such phenomena as sudden conversion, mysticism, glossolalia, ritual, and intense religious commitment may seem incomprehensible in terms of readily available psychological theories and therefore may spark the development of new ones. Alternatively, they may appear to be particularly vivid instances of processes of central importance to psychology. In this case, these phenomena become a challenge in that they demand an account from those who aspire to a comprehensive theory of personality and its development and change, motivation, emotion, cognition, perception, group behavior, attitudes, values, socialization, guilt, or virtually any other theme of common psychological interest. In particular, religion poses urgent questions about the relation between affective and cognitive processes and between the individual and his social environment.

Religion appears to share with abnormal phenomena this characteristic of presenting seemingly dramatic and unique manifestations which at the same time illustrate processes of central concern to any personality psychologist.

This distinction—between the seeming uniqueness of religion and its instancing of general problems in psychology—suggests alternative strategies in the study of the psychology of religion. One strategy begins with careful attention to the phenomena and to the development of useful descriptive categories to handle them. The other strategy turns to religious phenomena only after a theory has been developed in another segment of personality and behavior. Of the pioneer systematists at the beginning of this century who turned their attention to religion, James (1902) represents the former strategy, Freud (1913; 1927; 1934-1938) the latter.

The phenomena-based strategy generally, although of course not exclusively or necessarily, has been employed by those who were personally more "sympathetic" to religion, who therefore tended to claim a greater richness or validity for their "participant" observations.

The psychology of religion has been marked by a schism between these two strategies. Descriptive,

phenomena-based approaches of various kinds have made little progress toward developing genotypical categories useful for theoretical analysis. On the other hand, the "theoreticians" starting "outside" religion have made little use of the distinctions or other descriptive gains made by those interested in the phenomena.

While empirical research by either group has been limited—because practical, design, and measurement problems are formidable—the split, with regard to empirical work, is particularly wide. The theorists have apparently felt that any empirical obligation was already satisfied by demonstration—often clinical—of their theory before they applied it to religion or else by anecdotal application to instances derived from "armchair" observations or library resources. Empirical research by the phenomena-based group has tended to be limited to the most superficial data, such as church attendance or questionnaire self-report of "belief." Questions of greatest interest and importance have not been asked.

**Background and context.** Beyond the general psychological fascination which religion may have, impetus for work in the psychology of religion has come from at least three sources. The first, and perhaps the major, impetus has come from practical and theoretical concerns within institutionalized religion, especially Protestantism.

For example, the field of religious education has provided prominent focus, suggesting both problems and theories. Especially among Protestants in the early decades of this century, as sudden adolescent conversion became less normative, those concerned with religious education required that more attention be paid to the processes of religious development. This was encouraged by an optimistic, "liberal" theology which anticipated (in harmony with other progressive ideologies of the time) the possibility of developing ideal Christians, with the aid of scientifically discoverable principles. More recent "existential" concerns, emphasizing the role of "experience" in Christian nurture, as distinguished from intellectual instruction, has again brought new urgency to psychological questions.

During the middle decades of the twentieth century there has also been concern, especially among Protestant and Jewish clergymen, with finding sound psychological bases for dealing, as pastors, with personal and family crises. The acceptance of "depth psychology" has coincided with the development of a less optimistic "neo-orthodox" theology which emphasizes the darker side of human existence rather than its progressive improvement.

Furthermore, the general loosening of traditional

religious institutions and roles has sometimes left clergymen searching for a clearer pragmatic basis for defining, and perhaps even justifying, their role. This concern has coincided with greater institutional concern with recruiting, screening, training, and evaluating clergymen. The resulting research on the role, personality characteristics, and motivation of clergymen (Menges & Dittes 1965) has represented a new focus for the psychology of religion. [See PSYCHIATRY, *article on THE RELIGIO-PSYCHIATRIC MOVEMENT*.]

A second impetus, beyond the bounds of institutionalized religion, is a single frequently replicated empirical finding in social psychology: the positive correlation between indices of religion and of prejudice, authoritarianism, or other conservative attitudes. This finding has occasioned a continuing sequence of empirical and theoretical work for two decades. This has perhaps been provoked in part by the conflict in values aroused by the finding: religion is commonly regarded as a desirable value, and prejudice is not, and the official doctrines of organized religions generally repudiate prejudice.

The third impetus arises from the intrinsic connections between religion and psychology, especially clinical psychology. In many ways, religious and psychological enterprises have parallel, if not overlapping, concerns. Both call attention to, and offer conceptualizations about, human aspirations and apprehensions, about the relation of an individual to his total environment, about the processes of coping with stress, and about ameliorating the human condition. It is not surprising, then, that each should be intrigued by the prospective insights of the other.

Contemporary theologians (e.g., Roberts 1950; Tillich 1952) have systematically attempted to make theology take account of psychological formulations. Relatively little "adaption" in the other direction—exploitation of theological formulations for psychological research—has been attempted, although it would seem profitable (Hiltner & Rogers 1962). Theological formulations frequently include implicit or explicit psychological theories, including propositions about both the antecedents and the consequences of particular beliefs or other religious behavior.

**Philosophical and logical distinctions.** Some methodological attention must be paid to the important distinctions between religion and psychology. Psychological analysis of religion operates within certain clear and logically necessary, but not always understood, restrictions which distinguish it from other intellectual disciplines related to religion. There is sometimes a special problem

in relating, or distinguishing between, the psychology of religion and both philosophy and theology.

Logically, the distinction seems clear and has been made in similar terms by writers in the psychology of religion; James devoted an eloquent chapter to the point (1902). Psychology, philosophy, and theology may all be concerned with the same phenomenon, such as a particular belief or a particular ritual, but they ask different questions about the phenomenon. Psychological analysis is concerned with the psychological development and the functions of the belief or ritual. Philosophy is concerned with the correspondence between the belief or ritual and some criterion of truth, logic, or goodness, and theology, with its correspondence with such criteria as the will of God or other given norms of faith. The answers to the psychological questions do not necessarily imply or presuppose answers to the philosophical or theological questions. Even a thorough assessment of the psychological history and functions of a particular belief carries no ordinary implications for the "truth" or "faithfulness" of the belief; these must still be ascertained by the criteria appropriate to philosophy and theology. Both "true" and "false" beliefs may develop out of a particular pattern of social influences or personal motivation. The "genetic fallacy"—the evaluation of belief or behavior in terms of an analysis of its origins—has been soundly discounted by every major writer in the psychology of religion, including Freud (1927), who carefully used the term "illusion," when applied to religion, to refer to certain wish-fulfilling functions, not to religion's objective validity. Freud even acknowledged that science, a preference for which he argued on other grounds, was an "illusion" in this same sense.

Yet, despite the logical distinction—well accepted in principle—between psychology, on the one hand, and philosophy and theology, on the other, there remain at least two psychologically understandable grounds for the continuing confusion and blurring—perhaps more among the audience of the psychologist than by the psychologist himself.

One of these grounds for confusion is an unfamiliarity with, or a mistrust of, discrete disciplines of thought which claim correspondence, not with the "whole truth," but only with an abstracted and limited segment. Most socializing and reality-orienting processes accustom persons to regard reality as unitary and therefore to expect statements about reality to be similarly unified. Discrete disciplines or systems of thought are expected to be integrated. Differing statements—for example,

psychological and philosophical statements about the same belief—are perceived as mutually implicative. If mutual implications cannot be recognized, the statements are perceived as necessarily inconsistent.

The attempt to integrate different statements into a single statement or system often leads to an unwarranted syncretistic identification of terms (for example, "neurosis" and "sin" or "psychological anxiety" and "ontological anxiety") drawn from discrete psychological and theological systems (e.g., Roberts 1950; Tillich 1952). When such integration is not easily accomplished, then the psychological and philosophical (or theological) systems are seen as antagonistic, competing for the status of the *one* valid approach. With respect to Copernican astronomy, geology, and biological evolution, the result of long battles is the general acknowledgment that statements about history and function and statements about meaning and truth may *both* be true without having to be consistently integrated. But this acceptance is not yet universally accorded to psychological analysis. The view commonly persists that a belief must be either psychologically motivated *or* true (e.g., Havens 1961; Outler 1954).

A second psychological basis for confusion is a persistent notion in our culture, apparently related to Greek philosophy and perhaps to America's Puritan roots, that psychological history and motives are "unworthy" vehicles for truth. Epistemologically and theologically, it may be argued, in principle, that truth may readily arise through such psychologically discernible processes as social or motivational influences, as well as through pure reasoning; such a view would seem especially consistent with Christian notions of incarnation or Jewish emphasis on the importance of the community. But psychologically, the distinction between rational and emotional aspects of man doggedly persists in our culture and, hence, in psychologies of religion (e.g., Allport 1950; Clark 1958), with higher status accorded the rational aspects. Thus, a discipline, such as philosophy, that is concerned with intellectual processes and criteria may be accorded a superior role, to which the contributions of psychology must be accommodated [e.g., Outler 1954; see also KNOWLEDGE, SOCIOLOGY OF].

**Phenomena-based approaches.** The search within the phenomena of religion for useful descriptive and analytical categories has, ironically, been impeded by the dramatic strikingness of the phenomena. It has been found expedient to conceptualize religion largely in terms of particular phenomena: for example, conversion experience, church at-

tendance, personal prayer, assent to a particular dogma. These phenomena are so insistent and attention to them becomes so entrenched that it becomes difficult to break away from phenomena-based *ad hoc* categories, into the isolation of more genotypical and psychologically relevant variables.

For example, it is possible that some conversion, some church attendance, some prayer, and some belief—but not all of such instances—may share guilt-coping obsessional characteristics. Scientific progress may be gained by the development of such a category, cutting across groups of behaviors. But such progress has been slow because of the seeming dramatic insistence of the phenomena to be studied in their own terms—just as the descriptive, diagnostic categories of abnormal psychology have only slowly yielded to more “dynamic” variables, cutting across the phenomenological descriptions.

*“Religion” as a single variable.* The attempt to regard all religion as an integral phenomenon or as a single variable is the most significant and awkward illustration of the persistence of culturally convenient, but scientifically dubious, categories. A society finds it convenient and possible to group a great variety of behavior and institutions within the single category of “religion.” To its own frustration, psychological inquiry has commonly followed this practice.

Argyle (1958), for example, explicitly regards religion as a single quantifiable variable, with institutional membership or attendance, devotional practice, and orthodoxy of belief used as interchangeable indices. Other measures frequently used uncritically as a single index of “religion” are the religious-interest scale of the Allport-Vernon Scale of Values, scales such as Thurstone’s for assessing attitudes toward church, God, and Sunday observances, various tests of religious information, and self-ratings of religiosity.

Most attempts to define religion as a single variable also emphasize the uniqueness of religion as compared to other psychological and cultural phenomena. Such definitions tend to identify religion with mystical characteristics and also serve to exclude, by implication, the application to religion of psychological analyses applied to other types of behavior (Allport 1950; Clark 1958; James 1902).

But the usefulness or validity of such a global, single-variable definition of religion is not easily defended against a sophisticated theoretical viewpoint. As Johnson has dramatically argued:

In the name of religion what deed has not been done? For the sake of religion men have earnestly affirmed and contradicted almost every idea and form of con-

duct. In the long history of religion appear chastity and sacred prostitution, feasting and fasting, intoxication and prohibition, dancing and sobriety, human sacrifice and the saving of life in orphanages and hospitals, superstition and education, poverty and wealthy endowments, prayer wheels and silent worship, gods and demons, one God and many gods, attempts to escape and to reform the world. How can such diametrical oppositions all be religious? ([1944] 1959, pp. 47–48)

Several recent factor-analytic and correlational studies have suggested a single prominent factor, but it is a factor defined almost exclusively by attitudes toward religious institutions, the visible factor by which Western culture generally identifies religion. The few studies which have used more subtle indices than attitudes toward the church, and more sophisticated samples of persons more familiar with elements of religion other than institutional affiliation, have suggested that religion be considered as reflecting a multiplicity of factors (Dittes 1967).

Furthermore, empirical studies of “religion” defined as a single variable—primarily church affiliation and participation—have not tended to produce consistent, meaningful relations with other variables (perhaps because other variables are also grossly defined, in terms of such easily accessible measures as personality variables, age, education, diagnosis of pathology). Studies using such data typically show that religious involvement is “greater” among women, among young adolescents and those past middle age, among the less educated and less intelligent (when class differences are held constant), among members of the middle class, and among those scoring higher on measures of ethnocentrism and authoritarianism.

Definitions and descriptions which attempt to embrace in a single statement the religions of diverse cultures invariably seem to lose the critical and significant characteristics of any one. The number of facets of religious phenomena increases so greatly as one crosses cultural lines that cross-cultural definition and generalization are exceedingly treacherous. One perhaps ought to be pessimistic about developing a psychology of religion in general and perhaps instead learn more from studying cultural group and individual differences.

*Descriptive distinctions.* Among those committed to description of phenomena, the use of typologies has represented one attempt to define somewhat less global variables. These types are characteristically taken from those established by practitioners themselves—for example, distinctions between mystic, prophet, priest (e.g., see Clark 1958, chapters 12 and 13).

James (1902) proposed the much-quoted distinction between the religion of the healthy-minded and of the sick soul—perhaps more a distinction between personality types than between religious orientations per se. The distinction appears related to the manic-depressive continuum, with one end representing the extroverted personality ("positive thinking" in Norman Vincent Peale's terms) and the other a more depressed, introverted, openly conflicted person.

Pratt's (1920) distinction between subjective and objective worship has persisted, perhaps more as a haunting methodological dilemma than as a genuine phenomenal distinction. Objective worship, typified by the Roman Catholic mass, refers to intention and reference beyond the worshiper; subjective worship refers to self-conscious awareness of the effects of worship on the worshiper, as typified by much Protestant worship.

These typologies have not lent themselves to easy operational definitions, nor have they found themselves as part of more elaborate theoretical statements. Users of typologies have been content with typologies per se, rather than curious about the relation of the type with other variables.

Differing beliefs suggest another variable of potential psychological significance. But when these are taken in the language and the dimensions of the practitioners, they tend to emerge along a single conservative-liberal dimension, highly correlated with general "nonreligious" conservatism-liberalism and its known determinants. Other categories suggested by research in attitudes and perception outside religion, such as suggestibility, conformity, or dogmatism, may be more useful.

*Religion-religiosity.* Many writers have suggested the important distinction between "authentic" intensive inner religious experience, on the one hand, and routine peripheral religious activity, on the other. The distinction has been labeled internal-extrinsic by Adorno and others (1950), interiorized-institutionalized by Allport (1954), intrinsic-extrinsic by Allport (1959; Allport & Ross 1967), primary-secondary by Clark (1958), committed-consensual by Allen (1965; Allen & Spilka 1967), and religion-religiosity by many. The distinction reflects a value judgment and is analogous to one commonly made by religious participants themselves—especially by those regarded as prophets and reformers—who frequently call attention to the inverse relation between the two types of activity.

In empirical studies most measures used are of explicit, objective religiosity, usually involving par-

ticipation in, or attitudes toward, the formal religious institution, its overt activities, and its official doctrines. On the other hand, most theoretical efforts, including attempts at establishing distinctions between, and categories of, phenomena, are concerned with the more intrinsic, subjective religion—the inner "spiritual" life, personal attitudes and orientations, values, loyalties, and commitments. Indeed, assuming the present distinction, a major methodological weakness of most empirical research in the psychology of religion is the use of instances of extrinsic religiosity as indices of an intrinsic religious orientation (e.g., Argyle 1958).

Factor-analytic studies (e.g., Cline & Richards 1965; Allen 1965; Allen & Spilka 1967) tend to support the distinction between the explicit institution-oriented religiosity and more personal intrinsic religion. Most attempts to provide scales or other indices for each of these two elements have foundered on the likelihood that each is not a discrete variable but, like "religion" itself, a general rubric covering many independent variables. Allen (1965) and Allport and Ross (1967) report scales of extrinsic and intrinsic religion that have some construct validity (extrinsic religion was correlated with prejudice, but intrinsic religion was not).

*Psychoanalytic description.* Much psychoanalytic writing is essentially descriptive. It has been a common practice among psychoanalytical writers to identify themes thought to be of psychological significance in religious material. Religious symbols, activities, and legends have provided fertile ground in which both Freudian and Jungian adherents could discover disguised symbolic "meaning." A recent example (La Barre 1962) argues at length for the phallic symbolism of the snake in contemporary and historical cults and legends, including the Garden of Eden story. This work is classified here as largely descriptive because it focuses on the identification of a single variable rather than on the advancement of a theoretical understanding of the relation between that variable and others.

Freud's first writing on religion (1907) called attention to several descriptive similarities between religious ritual and obsessive-compulsive symptoms. The theoretical implications of common etiology and common functions have been extrapolated from this observation by others, for example, Ostow and Scharfstein (1954) and Jones ([1923] 1964, chapter 9).

*Theory-based approaches.* The two major psychological theories generally used in analyzing religious phenomena are both associated with Freud,

although neither was fully originated or developed by him. One theory emphasizes the psychological motive of dependence, the position of the mother, and the solicitous aspects of religion. The other theory emphasizes the psychological motive of hostility, the role of the father, and the demanding aspects of religion. Both theories reflect the fundamental hypothesis that the "religious life represents a dramatization on a cosmic plane of the emotions, fears, and longings which arose in the child's relation to his parents" (Jones [1923] 1964, p. 195).

The general distinction between the more solicitous and more demanding modes of religion has long been noted by many observers both within and without religion. Examples are the common adage of clergymen that their aim is to "comfort the disturbed and to disturb the comfortable" or the distinction between the creative, redemptive, justifying attributes of God—or the "saving," healing functions of religion—and the wrathful attributes of God—or the demanding, law-abiding, sanctifying functions.

Fromm (1963) has sharply contrasted these two theoretical orientations and has attempted to invoke them sequentially, in relation to changing social conditions, to account for changing emphases in early Christian centuries. Erikson (1958) has both distinguished and blended the theories in an intensive "case study" of Martin Luther's developing religious convictions. Bakan (1966) has proposed that religion represents the projection and management of *parents'* conflicts between personal "agency" motivations—including hostility to children—and nurturant motives.

*Theories based on dependence.* Dependence-based theories associated with Freud's second book on religion (1927) emphasize religion as a source of comfort, solace, or assurance in the face of external stresses and frustrations. A protective and projective parent is associated with deferred or fantasied satisfactions, especially in relation to keenly experienced frustrations. The religious response is one of submission, in imitation of such a figure as Jesus, the dutiful son.

Supporting data, beyond general reflections, are not overwhelming. Especially missing are what would be the most convincing data—correlations between evidence of significant life frustrations and submissive reliance in the framework of this particular kind of religious formulation. Some general evidence has accumulated suggesting generally "greater" religious involvement among groups such as the less intelligent and the economically deprived, who, one might infer, experience depri-

vation, frustration, and a sense of inadequacy. Evidence along these lines has been surveyed by Cronbach (1933), by Argyle (1958, pp. 145–154), and by Dittes (1967).

*Theories based on hostility.* Freud applied to religion the full range of his Oedipal theory and apparently believed that this application was confirmed by anthropological and historical materials he cited (1913; 1934–1938). Emphasis is placed on relations with a paternal god-figure and on coping with largely "inner" stresses generated by this relation, particularly hostility and rebellion. Various elements of belief and of practice are analyzed as allowing for the *expression* of such hostility, for its *control*, and for the consummating receipt of *punishment* and *forgiveness*. A prototype is the identification with a Christ-figure who assumes the role of God, yet submits to the father, is crucified, and reconciled through resurrection and ascension.

The subtle and complex variables of motivation and of religion with which this theory is concerned have so far eluded controlled empirical study.

*Projection and wish fulfillment.* Projection to God of attitudes toward a father are assumed by both theories. This assumption has given rise to empirical tests of various designs to discover whether there is a similarity between attitudes toward God and attitudes toward the actual father. The degree of correspondence discovered has varied widely, perhaps because the research has not carefully taken into consideration the theories' proposal that such projection takes place under conditions of particular personal motivation.

Wish fulfillment, or perhaps more accurately, "rationalization," is a general process postulated especially by the theories based on dependence. The degree and process by which conceptualization follows and is made consistent with motivation and practice has attracted varying formulations (e.g., Dunlap 1946). All tend to assume an independent "need to conceptualize" or a "need for consistency" among conceptualizations and between conceptualizations and behavior.

*Religion and ethnocentrism.* Perhaps the most effective fusion of empirical and theoretical work has developed from the repeated empirical finding of correlations between indices of religion and of conservative social attitudes—especially, because of the cultural importance given them in the mid-twentieth century, attitudes of anti-Semitism and racial prejudice. This correlation was brought into sharp focus and most of the subsequent developments were given direction by the work of Adorno and others (1950).

The finding has, among other things, stimulated attention to definitional problems, cited above, especially to the distinction between religiosity, which Adorno's measures reflected, and religion. Most theories, guided by an understanding of official religious doctrine, might expect religion to be directly related to liberal attitudes. [See ANTI-SEMITISM and PREJUDICE.]

Beginning with data in the Adorno volume, studies have regularly reported suggestions of a curvilinear relation between ethnocentrism and frequency of church attendance, with both non-attenders and the most faithful attenders showing more liberal attitudes than occasional attenders. If the most regular attendance can be interpreted as an index of more personal internalization of religious norms, beyond perfunctory institutional loyalty, then this may be some evidence of the theoretically expected relation between intrinsic religion and liberalism. Other evidence awaits the definition and measurement of such elements of intrinsic religion as faith, hope, love, trust, freedom, etc.

*Personality variables.* The relationship between religion and ethnocentrism has led to theory and research aimed at designating the personality characteristics that underlie both variables and mediate the relation. Research findings suggest that a person for whom both conservative ideology and conventional, institution-based religion are functional is a person with a "weak ego" or "severe superego," who is threatened by external circumstances or internal impulse and therefore likely to be responsive to the unambiguous external controls, structures, and supports provided either by a religious institution and its ideology, rituals, and moralisms or by the strict categorizing and self-enhancement provided by ethnocentric doctrines.

Such an interpretation of the function of religion is supported by a wide range of empirical reports of the correlation between religion (especially as measured by institutional loyalty and adherence to conservative doctrines) and lower intelligence, disrupted emotional life, suggestibility, constricted personality, and awareness of personal inadequacy (Dittes 1967). These findings, suggesting that religion may attract the relatively inadequate and helpless, may be less shocking than first supposed to the exponents of religious traditions whose highest religious celebrations commemorate a captivity or a crucifixion and who generally preach man's fallen state and fundamental helplessness.

An extension of this general view also seems to account for a range of dramatic phenomena, such as glossolalia, sudden emotional conversion, faith

healing, and trance states. Reports, though meager, of personality characteristics and of environmental characteristics associated with such participation suggest the existence of a general trancelike, regressive "ego constriction" that produces greater expression of impulses and greater responsiveness to suggestion and social influence. [See HYPNOSIS; HYSTERIA; PERSUASION; SUGGESTION.]

Finally, the relation between religion and ethnocentrism has stimulated further attention to defining cognitive variables and especially to making the distinction (e.g., Rokeach 1960) between the content characteristics of a belief or attitude and the content-free or structural characteristics of the style, such as the openness or the dogmatism with which it is held. This has led to the hypothesis that religion is related more to elements such as the need for closure than to the conservative elements of ethnocentrism. [See PERSONALITY, POLITICAL, article on CONSERVATISM AND RADICALISM; SYSTEMS ANALYSIS, article on PSYCHOLOGICAL SYSTEMS.]

## RELIGIOUS OBSERVANCE

Religious observance includes all overt kinds of religious behavior. This article will consider the main sociological and psychological sources of variation in religious observance. Sociological factors include historical trends, social class, and membership of minority groups. Psychological factors include age, sex, and personality traits. We shall

consider studies carried out between 1900 and the present day in Great Britain, the United States, and western Europe. Research in this area shows the extent and patterning of religious activities in the population and makes it possible to test theories about the causes of religious behavior.

**Measures and indexes.** Frequency of church attendance is the most widely used index of religious observance. It can be assessed by actual observation, but questioning is the more usual method. If "How often do you go to church?" is asked, there is often some inflation of the true figure. "What did you do last Sunday?" is a better way of introducing the issue and gives a more accurate estimate of the behavior of a large group of people. This index is open to the further difficulties that some denominations exert greater pressure for attendance and that some people go to church for nonreligious reasons. Supplementation by other measures is therefore valuable.

One of the most important of these is the amount of private religious activity, such as saying prayers or reading the Bible. This needs to be assessed by very precisely worded questions, or again there will be exaggerations of the true amount. The profile of religious activities of different kinds may be very informative; for example, the ratio of private observance to church attendance is greater for Protestants than for Roman Catholics, and the same is true for women as compared with men. Church membership is useful for making historical comparisons, but the criteria for membership are different for different denominations, Roman Catholics and Jews being the most lenient. Furthermore, these criteria change with time: the apparent American Protestant revival in the first quarter of this century was due to changes in the definition of membership, with the result that more members were counted (National Council . . . ). Other sociological indexes include contributions to church funds (in relation to average income) and numbers of publications on religious topics, both of which can be used to study historical changes. Attitude scales, measuring attitudes toward the church or toward religion, correlate well with church attendance. Indeed, factor analyses of various indexes and measures suggest that frequency of attendance is the most representative single measure; it is also the one most often used in research.

**Variations in religious observance.** Variations in religious observance raise questions of the type, Why does A go to church while B does not? The answer may take three possible forms.

**Social learning and group pressures.** If a person is brought up in an isolated community where everyone takes part in the same religious practices, there is no difficulty in predicting his religious activities. In general a person will be greatly influenced by his family, especially if he has a close relationship with them and lives at home: correlations between attitudes of parents and children who are at student age are in the range of .40 to .60. People are also influenced by the social norms of groups to which they belong outside the home. If family and friends conflict, the influence of each is weakened, oscillation between them may be the basis for conversions and reconversions, and the final outcome will depend on which attachment is the stronger as well as on how far the orientation of each fits the individual's personality.

**Individual differences in personality.** Every ideology and its associated practices meet some needs and fail to meet others. For example, a very aggressive person is more likely to support capital punishment than pacifism. The same is true of religion, though the needs and personality mechanisms involved are many and complex (Argyle 1958; 1964). These can be deduced from findings about the religious practices and beliefs of people with different personalities.

**Socioeconomic categories.** Pressures to conformity exist within all social groups, although personality may cause some individual variations in behavior. But statistical differences in religious observance are also found to exist according to social class, region, and other socioeconomic categories. Such differences can often be accounted for by the different psychological situations of people in these groupings, for whom religious practices will have a very varied appeal. In other cases there may be a historical explanation.

### Sociological variables

**Denominational differences.** For our purposes a fourfold classification of religious observance is most useful. First, *conservative religion* includes Roman Catholics, Lutherans, and some Episcopalians and Anglicans. Members of this group, as well as having certain characteristic beliefs, have a high rate of public worship combined with a low rate of private worship. The clergy have considerable power and are held in high regard; services are formal and ritualistic. Second, the main *Protestant churches*, such as the Presbyterians and Methodists, have less ritual and formality of worship, place more emphasis on sin and guilt, and are more active in evangelism. Individual clergy-

men have their followers, but they have less formal power. The level of church attendance of Protestants is much lower than that of Roman Catholics in most countries, but when Protestants are in a minority, as in France, they actually have higher attendance rates than Roman Catholics (Fogarty 1957). Third, *sects* are at the furthest end of a dimension that has Roman Catholics at one extreme and Protestants in the middle; services are informal and highly emotional, and there is little church organization. Finally, *liberal religion* includes Unitarians, most Jews, Quakers, and some people of no religious affiliation at all. Church attendance is low in this group and is neither ritualistic nor emotional, just as the religious attitudes of this group are more cognitive than emotional.

It is impossible to provide any brief explanation of these differences. It could be said that each type of religion has arisen under specific social conditions and attracts a particular type of person. There is also a developmental relation between them. Sects represent the primitive form that emerges spontaneously under the influence of a leader; they gradually become more formal and develop into churches. Both sects and Protestant churches are splinter groups from established churches.

An example of the differences between religious bodies is provided by nationwide surveys of public and private observance in Great Britain (Table 1).

**Table 1 — Public and private religious observance in Great Britain, by denomination, in per cent**

	Weekly church attendance (1947)	Regular private prayer (1950)
Roman Catholics	52	68
Nonconformists	14	43
Church of England	8	48

Source: Adapted from Argyle 1958, p. 159.

**Historical factors.** Fairly extensive data on religious observance in the United States and Great Britain since 1900 are available from records and social surveys. In Great Britain weekly church attendance dropped from 11.5 per cent of the population to 3.5 per cent over the period from 1900 to mid-century. Membership and proportion of average income donated fell 50 per cent. This decline was, however, largely confined to the Protestant churches; the Roman Catholics showed little change. Analysis of membership and Easter communicants shows a continuous decline to 1950, followed by an increase to 1957; it has subsequently leveled off (Argyle 1958). In the United States there was a slow drop in membership (corrected to allow for

changing definition) from 1900 to 1943, and analysis of donations during this same period shows a 50 per cent drop in percentage of income donated. However, both donations and church attendances started rising in 1943 and have continued to do so. The proportion of Roman Catholics in the United States has increased from 16 per cent to 22 per cent of the population since 1900, and there has been a great expansion in a number of small sects, although many of these sects have become more like Protestant churches during this period (Thomas 1963). In France there has been a slow but steady decline in religious observance since 1850, especially in the urban areas that have become most heavily industrialized. This trend has resulted in the very great differences between town and country reported below. About 94 per cent of the population are baptized Roman Catholics, but only about 40 per cent of them attend Sunday Mass regularly (Boulard 1954).

What is the explanation of these historical changes—that is, a general decline since the second half of the nineteenth century and a temporary recovery in the 1950s? The growth of cities, industrialization, and the development of a culture that is primarily materialistic and scientific are probably some of the factors. There has been considerable variation in economic prosperity since 1900, but contrary to the expectation of some people, this appears to have no regular relationship with religious observance. There was no increase in religious observance during the depression (Kincheloe 1937); on the other hand, there has been an increase during postwar prosperity. It is true that the American sects expanded during the depression, but they also expanded before and after it. It has been alleged that the postwar increase in religious activity is due to prosperity, but the increase in Great Britain stopped in 1957, despite continuing prosperity; in any case, stronger evidence is needed to support this theory. Does war affect religious observance? There is no clear evidence of nationwide changes owing to war. On the other hand, men involved in military action often pray when in danger, and many become more religious later—though sometimes in a non-institutional manner—while others become less religious.

The decline in religious observance from 1900 to midcentury may well be due to changes in child rearing (Bronfenbrenner 1958). Protestantism has an appeal to personalities with strong superego and guilt feelings, while Catholicism appeals to people who are dependent on authority. Trends in child

rearing have made both types of personality less common. However, the increase in religious activity in the United States and Great Britain since mid-century is more difficult to explain. It is noteworthy that this increase has been in the more liberal type of religion and that other religious bodies have also moved in this direction. One factor may be the greater emphasis the churches have put on social activities, with a corresponding appeal to the emergent teen-age group, but at present there is no accepted explanation.

**Social class.** There are excellent social survey data concerning class differences. In Great Britain it is consistently found that the higher the social class, the more frequent is religious observance. According to a survey taken by Odham's Press in 1947, weekly church attendance was reported by 13.4 per cent of the working-class respondents, 16.3 per cent of lower middle-class, and 19.4 per cent of upper-class and upper middle-class respondents (cited by Gorer 1955). Similar results, though with smaller differences, are found for private observance and affiliation. In the United States there is a similar relationship between religious activity and social class: in one recent survey 34 per cent of the Protestant, semiskilled workers were regular church attenders, compared with 47 per cent of professional people; the corresponding figures for Roman Catholics were 66 per cent and 81 per cent (Lazarwitz 1961). In France rather greater differences are found in the same direction; about 10 per cent of manual workers are regular attenders at Mass as compared with about 50 per cent of managerial and professional workers (Pin 1956).

There are also class differences in denomination. In Great Britain the Church of England draws more members from higher up the social scale, while the reverse is true of the Roman Catholic and Nonconformist churches. In general, the sects appeal to the most underprivileged, although this is not true of Christian Science. The differences are not great: 55 per cent of upper middle-class people claim to be Anglican versus 48 per cent of working-class people. There are also differences between members of individual churches in a given denomination. In the United States, while over-all class differences in observance are smaller than in England, class differences in denomination are greater. There is a definite hierarchy, with Episcopalians, Presbyterians, Congregationalists, and Methodists at the top, followed by Lutherans, Baptists, and Roman Catholics, and certain sects at the bottom of the socioeconomic system. There is also a spread within each church; Roman Catho-

lics and Methodists, in particular, are drawn from all classes. In a particular town or area the class segregation may be fairly sharp: a survey of part of California found that the percentage of unskilled laborers was 84 per cent among Pentecostals, 19 per cent among members of the Assembly of God, 15 per cent among Baptists, and 1 per cent among Congregationalists (Goldschmidt 1944). In European countries, such as Germany, the Protestant minority are of higher social status than the Catholics (Fogarty 1957).

These findings can be summed up by saying that the upper and middle classes are more orthodox and formalistic, while the working classes are more emotional in their religion. Such differences can also be found within the same denominational groups (Vernon 1962).

It has been shown in the United States (Pope 1942) and observed in other parts of the world that small sects usually start among the very poor. As the members become more prosperous, the church changes its character to become more like an established Protestant church. The less prosperous members then break away to form another sect, which goes through the same cycle again. Social mobility of a whole group of people may thus result in a change in the character of their church. Mobility of an individual, however, especially upwards, may lead to his changing to another denomination.

The single most important fact here is that poor people are not, in general, more religious than others. This clearly contradicts the many theories, of which those of Marx and Freud are the best known, according to which religious belief is the outcome of social frustration. However, such theories might help to explain the sect type of religion, in which tension-discharging meetings and beliefs with a strong element of compensatory fantasy are typically accompanied by the expectation of an imminent end of the world and consequent improvement in the lot of the members. The explanation of the changes in churches as their members move up the social scale is simply that as people become more prosperous and settled their need for tension-reducing services and compensatory fantasies declines. Thus it may be that the Church of England has consistently alienated the industrial working classes of Great Britain by its middle-class and generally conservative outlook; this, at any rate, would partly account for its relatively small working-class membership.

The higher social class of the members of the major Protestant churches may be explained by

Max Weber's theory that Protestantism develops certain attitudes conducive to capitalism, perhaps through Protestant child rearing, which engenders greater achievement motivation.

**Minority groups.** Minority groups are often underprivileged and show an above-average level of religious activity, especially in sect religion, as in the instance of the American Negroes. African Negroes also have a taste for emotionally expressive types of religion. Another sociological factor here may be that of being uprooted from the rural or tribal community: new arrivals at the outskirts of large towns are found to be active in sect religions in Europe and Canada as well as in Africa (Mann 1955). Finally, immigrant minority groups may import their previous religious practices, which are retained and encouraged in order to bind the group together: indeed, the church may act as a kind of community center.

Turning to otherworldly matters on the part of underprivileged minority groups has been criticized on the grounds that it does not help to solve their real grievances and indeed distracts attention from them (Myrdal 1944). In some cases, however, churches and their leaders have taken part in non-violent resistance and other political activities designed to advance the interests of minority groups. A further explanatory principle that should be mentioned in this connection is the theory of the quest for ego identity. Erikson (1956) has postulated a need for a clear and satisfactory picture of the self; and this picture is partly based on the reactions of others. Thus uprooted migrants, who have no place in society, can be greatly helped by sect membership, where up to 15 per cent of the members can be officeholders (Mann 1955).

**Town and country.** Surveys from several countries show a clear difference between town and country: the larger the community, the lower the level of religious observance. This tendency is strong enough to counteract another factor in the United States—that is, the tendency of Roman Catholics to be concentrated in the cities. In Great Britain the weekly attenders vary from 12 per cent in large cities to 17 per cent in small towns (Gorer 1955). In France there is a rather greater difference between town and country; in country areas about 60 per cent are regular attenders of Mass, compared with 25 per cent or less in the cities (Boulard 1954; Pin 1956). The most probable explanation is simply cultural lag: the slow decline in religion in the first half of the century has not yet affected rural areas. A further probability is that the churches are still maintaining a rural

world picture and have not yet come to terms with the modern industrial world; this is particularly true of the Roman Catholic church in France.

**The mass media and evangelism.** Public meetings are the traditional means of evangelism. They have not wholly been replaced by radio and television and are not likely to be. Their great advantage over less direct means of communication is their ability to arouse emotional excitement; there is considerable psychological evidence to suggest that for the change of deep-rooted attitudes and beliefs, emotional arousal is very effective—especially when combined with a persuasive message and social pressure (Sargant 1957). Studies of evangelical meetings show that the higher the emotional temperature, the greater the percentage of people converted. At Billy Graham's campaigns in Great Britain, 5.3 per cent made decisions at the larger meetings, compared with 2.3 per cent at smaller ones and with 0.8 per cent at overflow meetings. However, when people are converted by highly emotional methods, the proportion of those who are permanently converted is less. About one-half of Graham's converts (excluding those who were church attenders already) were still active a year later. The comparable figure for the nineteenth-century revivals was one in six or less (Starbuck 1899).

The conditions for conversion at a public meeting are as follows: large, crowded meetings; a highly prestigious preacher, skilled at arousing emotional states; a message showing how a change of behavior or belief will reduce the anxiety or guilt aroused; and pressure exerted by assistant evangelists. Those most likely to be converted are females between 13 and 21 years of age who have strong guilt feelings and no background of religious instruction.

The explanation of religious conversion takes two forms, depending on whether it is "gradual" or "sudden." Gradual conversions are nowadays the more common and can be interpreted in terms of social influence and social learning: for example, exposure to the religious ideas of an educational institution or peer group. Sudden conversions usually occur during adolescence and usually among people with strong guilt feelings. What probably happens is that young people's guilt feelings are heightened by the preacher; they are then especially receptive to Protestant doctrines of salvation that promise relief of guilt feelings.

It is not known to what extent religious behavior and beliefs can be affected by radio or television. The experience with political and other attitudes

is that actual conversion is rare, though there can be minor changes and the creation of beliefs on new topics, while exposure over a long period can bring about a slow erosion of attitudes that previously flourished unchallenged.

### Psychological variables

**Sex differences.** Women are more active in religion than men, but the extent of the difference varies with the level of activity, the denomination, and the type of observance. In the United States, where there is a high level of observance, about 50 per cent of all women and 42 per cent of all men attend some place of worship every week, giving an attendance ratio of 1.19 women for every man. In Great Britain there is a lower level; the corresponding percentages are about 17 for women and 11 for men, giving a ratio of 1.55 women per man. One possible explanation of this difference in ratios is that when there is more observance, conformity pressures are greater, so that individual differences are reduced.

The sex ratio also varies with denomination. In the United States the ratio of female to male members varies from about 1.10 for Roman Catholics and Lutherans to 1.35–1.55 for the main Protestant denominations to 1.55–2.10 for the sects. This can be explained partly in terms of the conformity pressures mentioned above: when the clergy are more powerful, the rate of attendance is greater and individual differences less.

The sex ratio varies with types of observance. The ratio is least for the public aspects of worship, greatest for the more private. In the United States the ratio of women to men for saying private prayers is about 1.65, compared with 1.19 for church attendance. Again, this is what would be predicted by the conformity theory.

It has not yet been explained why there should be a differential sex ratio at all. There are two possible lines of explanation. First, women have stronger consciences and stronger guilt feelings and therefore respond more strongly to Protestantism. One study finds a strong correlation between guilt and frequency of church attendance among Protestant women (Argyle 1964). Second, when God is presented as like a father, he should have a greater appeal for women, if the Oedipus theory is true. The smaller sex ratio for Roman Catholics would be expected, since they are provided with a mother figure as well as a father figure. Thus both of these theories may account for the greater sex ratio among Protestants.

**Age differences.** Religious observances and beliefs are different at each stage of life. In child-

hood (3–10) there is considerable activity, including praying for the gratification of immediate needs, holding fairy-tale religious beliefs, and sharing the religious activities of the family. In adolescence (10–18) there is often a good deal of conflict, as a result of exposure to differing influences and ideas. It is not so much a period of religious activity as a period of decision. Although most conversions to religion occur during this period, it is probable that there is an equal number of reconversions, since there is no over-all increase in religious observance. Religious observance at this age, however, is marked by rather greater emotional fervor than at other ages, and young people will readily take part in the conversion of others.

During young adulthood (18–30) there is a slow decline in religious observance: 25–35 per cent of those religiously active at 18 are inactive at 30. On the other hand, a few people have their first conversion during this period. During later adulthood (30 onward), there is a steady increase in religious activity, so that virtually 100 per cent of people of 90 and over are religiously active (Cavan et al. 1949). This increase has not been found in some recent American surveys, probably because the increase in observance since 1943 has masked aging factors as deduced from cross-sectional surveys. However, the increase with age has been shown by surveys at other times and places, as has the definite reversal in trend at 30–35. Among older people both the emotional and intellectual aspects of religion are feeble, and observances have long become habitual. They often take an active part in the organizational aspects of church life [see AGING, article on SOCIAL ASPECTS].

The explanation of the religion of later adulthood is the easiest: older people become anxious about death, and religion helps to reduce this anxiety. There is extensive support for this view: old people who are religious are better adjusted, and as people become older they increasingly give reassurance of immortality as their reason for church attendance. The observance of adolescents is differently motivated: by the relief of guilt mechanism; by the projection of the superego onto God or onto the clergy; and by cognitive needs to understand basic problems of life, for which only religion provides answers. The relatively low rate of religious observance of the 30–35 age group is due to the relative absence of these motivations, combined with a preoccupation with earthly problems involving occupation, family, and money. The decline in observance among Roman Catholics in the 30–40 age group has been attributed to a further factor—conflicts about birth control.

**Personality factors.** Although the findings on the subject of personality factors as related to religious activity are rather scattered and inconsistent, certain generalizations can be put forward. First, Protestants may be more guilt-ridden and intrapunitive than Roman Catholics. This is supported by the finding that Protestants have a higher suicide rate than Catholics (Dublin & Bunzel 1933); although this difference is related to the fact that suicide is forbidden by the Roman Catholic church, this fact itself needs to be explained. Moreover, Protestants have lower crime rates, especially for aggressive crimes, as compared with Roman Catholics; their mental patients are more often depressed (Farr & Howe 1932) and their converts are preoccupied with guilt before the event (Starbuck 1899). Second, in general, churchgoers are more conformist, suggestible, authoritarian, and right-wing in politics than others. This is particularly true of the members of the larger established churches; it is least true of Quakers, members of other churches of the liberal type, and sect members (Adorno et al. 1950). Third, young religious people are somewhat more neurotic than others, while old religious people are rather better adjusted. Finally, among psychotic patients, about one in seven is preoccupied with religious ideas or practices (Farr & Howe 1932), and many religious leaders and innovators have been found to have psychotic symptoms.

My own investigations of religious activity indicate that two psychological mechanisms may account for a number of these findings. The first of these two mechanisms has been introduced already: the relief of guilt feelings by the acceptance of Protestant doctrines of salvation. Frequency of church attendance has been found to correlate with strength of guilt feelings for women only (Argyle 1964). It seems likely that this mechanism operates for female Protestants, especially between the ages of 14 and 30, and that this accounts for the findings on neurosis and suicide.

The second theory states that internal conflict between the self and the superego results in the latter becoming projected or externalized onto clergy, saints, or God. In one study Roman Catholics were found to have a greater conflict between self and superego than others, and it has been shown that they make greater use of projection as a defense mechanism (Dreger 1952). This may account for the greater power of the Roman Catholic clergy, the relatively greater amount of Roman Catholic public observance, and the more severe Roman Catholic image of God.

## RELIGIOUS ORGANIZATION

Religious organization is the complex of institutionalized roles and procedures which regulate the relations of men with the supernatural order, however such an order may be conceived. It may involve the regulation of religious practice and the promulgation of true, and suppression of false, doctrine; procedures for the recruitment, education, and professional socialization of religious specialists; the structure of authority among them; the basis, extent, and nature of their authority over the laity and its territorial and temporal coordination; the control of religious places, periods, premises, and equipment and such property and temporalities as accrue in the establishment of this control.

Despite the wealth of religious scholarship, there are very few studies of religious organization, and of this exiguous literature very little employs sociological analysis. Organization theory as developed in sociology has little relevance to non-Western religions. In Western Christianity and Judaism, religious roles and procedures constitute articulated structures which, with increasing self-consciousness, approximate to bureaucratic models; however, even in the West, the extent of this approximation is limited by the inherent nature of the religious quest. The patterns of affective neutrality, role specificity, performance expectations, self-orientation, and even universalism, which characterize the dominant organizational mode of Western society, are all, in greater or lesser degree, alien to religious institutions, roles, relationships, and values. The comparative historical analysis of Max Weber, although not specifically concerned with organization as such, and the more typological stud-

ies of Joachim Wach remain the outstanding works in this field.

In non-Western societies, religious activities are usually an intimate part of the life of the local community and lack an independent and articulated organizational structure. There may be loose association between communal activities and those of regional religious centers. Local religious agents operate within the community, and their responsibilities do not extend beyond it. Family, kinship, tribal, local, and even national cults represent a high degree of convergence of political and religious institutions; such cults were found widely in ancient civilizations, as documented by William Robertson Smith (1889), N. D. Fustel de Coulanges (1864), C. W. Westrup (1939-1954), Marcel Granet (1922), Martin P. Nilsson (1941-1950), and (more sociologically) by Max Weber (1922a) and Joachim Wach (1944). The development of a national cult is apparent in the Old Testament, and Bellah (1957, chapter 4) makes evident its importance in Japanese Shintoism.

**Religious authority in East and West.** Religious roles are universal, but they are not always performed by full-time specialists. The part-time functionary has less opportunity than the full-time specialist to acquire authority and thus can be less adequately integrated into an organization. Autonomous religious authority is likely to arise only where the mystical and magical offices of religious functionaries are regarded by secular authorities as indispensable for the legitimation of their power. This was a function of the Brahmins in early Hinduism, but they did not evolve a religious organization of the rational hierarchic type; the preeminence of religious status may itself have limited such a development. The Brahmin caste was a hereditary guild which monopolized religious functions; religious power tended to be localized and particular, diffused within the wider society but not subjected to division of labor and hierarchization within the stratum.

In contrast, Christian priests lacked this ascriptive basis of status; the hereditary principle was checked by the imposition of celibacy; charisma was attached to the office rather than to the person; and appointment to office was often dependent on political agencies. Under these circumstances, religious functionaries often stood in a relationship of uneasy interdependence with political authorities. Religious authority, limited in its exercise over secular society, developed as a hierarchic structure within the religious institution itself. The religious institution gained coherence by modeling itself on the political structure, which, in certain circum-

stances, it came to supersede or transcend. The articulation of responsibility within the religious institution necessarily involved insistence on the coherence and exclusiveness of doctrine and liturgical practice. This insistence created divisions in Christianity after political and coercive power was lost to the church, but the principles of coherence and exclusiveness became characteristic of all the separate Christian organizations.

### Leaders, members, and organization

An important variable affecting religious organization is the extent to which religion is founded on prophecy. Certain religions, such as Christianity, rely on conversion to the teachings, ritual, ethics, and example of the prophets who founded them. In religions which do not trace their foundation to a prophet, allegiance is determined largely by ethnicity, though even within the traditions of founded religions, insulated religious communities arise in which birthright and, hence, ethnicity become the principal, if not exclusive, criteria of eligibility for participation (Hostetler 1963; Francis 1948). The degree of voluntary commitment which they demand clearly differentiates founded from unfounded religions. Christianity almost always requires voluntary commitment, however formal this may be in practice. In traditional Hinduism, by contrast, voluntary acceptance of ritual obligations by the unentitled would be inconceivable, while their neglect by Hindus, with the implied rejection of caste obligations and the status claims of Brahmins, could bring only spiritual perdition and social ostracism (Weber [1921] 1958, pp. 8 ff.; Hutton [1946] 1964, chapters 6 and 7). Although the convergence of ethnic, social, and religious status in Hinduism was challenged by the development of distinctive cult practices, such as the Lingayat (Weber [1921] 1958, pp. 298 ff.), these cults also lacked systematic organization and have frequently been vulnerable to reabsorption into the caste structure.

**The case of Judaism.** In Judaism after the Diaspora, the destruction of the Temple and the disappearance of priestly authority made religious practice the distinguishing criterion of Jewish identity and the focus of ethnic and community values. Jewish communities were organized around the synagogue, which became the surrogate of the Temple, as did the rabbi of the priest. Rabbinical patriarchs superseded the priestly hierarchy, but once they were deprived of political power and dispersed in relatively small communities, the principal function of rabbis became that of interpreters of the law, and it was from this function that they

derived their authority as religious and community leaders. A high degree of uniformity of faith and order rested on principles drawn from the synagogical service. Whereas the prophet legitimated his authority in terms of divine inspiration and the priest in terms of hereditary right to perform sacrifice, the rabbi's claim rested on his knowledge of the law, which covered ritual, taboos, and civil matters, such as marriage, divorce, and inheritance.

Thus, the rabbi's role traditionally had community significance rather than specifically religious significance. This fact and the fact that the rabbi's role is open to all Jewish males who undergo appropriate instruction are conditions which limited the development of hierarchy, especially when we take into account the dispersal of Jews into small communities. At a relatively late date, rabbis in dispersed European communities formed wider associations, but even today "there is . . . little formal hierarchical organization . . . and the role itself remains functionally diffuse . . ." (Carlin & Mendlovitz [1958] 1960, p. 379). Discrimination and persecution enhanced the significance of synagogical organization and of religious ritual and law for European Jewry, whereas in less intolerant contexts, Jews let their observance of law and ritual decline and became more fully assimilated to the host society (Strizower 1962). In industrial societies, modern Judaism has increasingly adopted the type of organization characteristic of Christian denominationalism (Steinberg 1965). This process has been facilitated by the fact that authority resides very largely in the individual congregation (Sklare 1955, pp. 40-42). Rabbinical authority has declined as the rabbi's functions have grown less relevant to modern life. Although Judaism is today essentially a nonconversionist religion, the secularization of Jewry has led to extensive diversification of religious commitment on the part of individual Jews and given modern Judaism some of the characteristics more typical of founded religions.

**The problem of authority.** All religions have had the problem of enforcing their own practices and eliminating indigenous magical preoccupations. The acceptance of the ethical prescriptions of Buddhism originally implied the cenobitic life, and initially Buddhism lacked organizational precepts for the control of the laity; thus its development as a lay religion depended on political support. Without a theology or a liturgy, Buddhism, in its lay expression, was less protected than most religions from the accretion of indigenous magical traditions; hagiolatrous, idolatrous, and logolatrous tendencies developed, especially in Mahāyāna Buddhism. Abbots acquired religious and political con-

trol of lay populations, most notably in the lama-series of Tibet.

Christianity, with its strong authority structure, and in the context of an increasingly rational climate of thought, was widely successful in eliminating magical practices and in enforcing religious observance—sometimes, where it has dominated political affairs, by punitive measures. But even Christianity has been less successful in its mission territories; and among the country people of even long-settled Christian areas, and among unacculturated urban groups, magical ideas persist, especially in non-Protestant countries (Siegel 1941; Bastide 1960).

### Hierarchy and the priestly function

Religious institutions may attain a high degree of organizational, doctrinal, and ritualistic consistency from the association of religious roles with political or legal roles or in imitation of political structures.

**Christian hierarchies.** The Christian church, growing up outside the political framework of the Roman Empire but later becoming affiliated to it, evolved an autonomous hierarchy. Its organization withstood the subsequent fragmentation of the previously supporting political structure and in some circumstances assumed political authority. In contrast to the profuse variation evident in Far Eastern religions at local and regional levels, Christianity, in spite of its numerous divisions, appears inherently more monolithic in structure. For example, simultaneous allegiance to Taoism, Confucianism, and Buddhism has occurred in China and, with the addition of Shinto, in Japan. Among the world's religions, organization based on a universalistic principle of rigorously exclusive voluntary belief is a characteristic only of Christianity and Islam (Judaism, being ethnically based, is not universalistic).

Christianity inherited exclusiveness from Judaism but soon accepted the universalistic principle of voluntary commitment. Early Christians were organized as self-chosen autonomous congregations of saints, probably under colleges of presbyters. Priestly functions, partially derived from Hebrew sources, developed with presbyters and deacons instead of the Aaronic priests and Levites, according to the *Epistle to the Church at Corinth* of Pope Clement I (fl. A.D. 96). Whether the early leaders were congregationally chosen or were itinerant apostolic deputies, and what rights congregations had over them are questions which are disputed. Some local leaders, such as Ignatius of Antioch (fl. A.D. 115), claimed considerable eminence and from metropolitan centers acquired

authority over surrounding areas. Thus a monar-chic type of episcopacy developed. Bishops were only gradually subordinated to the authority of metropolitan centers and finally to the papacy (Telfer 1962). The hierarchy of the imperial state influenced the development of religious hierarchy. Struggles between rival centers, which often espoused mutually heretical doctrines, finally resulted in increased centralization and coordination, the growth of which was also facilitated by the metaphysical doctrine of one universal church, of which particular congregations were seen as localized expressions. Hierarchy thus extended both above and below the episcopal level, and the pope came to appoint men to bishoprics (unless a temporal authority usurped this power) and instituted the metropolitan title *legatus natus*, which was normally conferred on archbishops as a reinforcement of papal control.

The modern Roman church declares that a bishop has sovereignty in his diocese; that the episcopate is of divine right; that the pope cannot arrogate episcopal rights; and that bishops have not become his instruments. However, it also asserts that the pope, as the universal ordinary, has power over all churches and that bishops owe personal allegiance to the holy see (Rahner 1964; Rahner & Ratzinger 1961; Telfer 1962). The nicety of theological argument cannot conceal the reality of papal power; indeed, the laity as such has no influence in the appointment of bishops in the Roman church. However, in the autocephalous Greek Orthodox church the laity retains vestiges of at least nominal control, although real power is in the hands of the bishops, whose executive functions are vested in an annually appointed synod of 12 of their number under the permanent presidency of the archbishop of Athens (Hammond 1956, chapter 4). In the Roman, Orthodox, and Anglican churches, the religious hierarchy stands above the laity and gives these churches the character of objective, external, and transcendent institutions (Troeltsch [1912] 1931, pp. 331–343; Yinger [1957] 1961, chapter 6).

**Islam—a society under law.** Although Islamic society was theocratic, the absence of priestly roles meant that hierarchization occurred in its political rather than in its religious institutions, which never acquired autonomy from the political system established in the name of the prophet. Political power was consolidated with religious sanction, toward the achievement of a new integration of society transcending the tribal level (Watt 1961; Levy [1931–1933] 1957, chapter 1). The prophet's successors, the caliphs (*imāms*), were, in orthodox

Sunni theory, exponents of the divinely inspired law, and their function was to preserve religion and exercise leadership (Ibn Khaldūn [1375–1382] 1958, vol. 1). In early Islam caliphs held the office of judge, later delegated, and came to exercise royal authority at certain periods. The Sunni caliphs enjoyed no sacredness of character; they were never popes, as medieval Christians supposed (Daniel [1960] 1962, p. 225) and as was supposed of the sultan of the Ottoman Empire in the eighteenth century. (Some Shi'ite sects regard the caliphate as a divine institution, but their attempts to secure power for the descendants of Ali met with little success: the Fatimids of Egypt were the only important Shi'a caliphs.) Hierarchization occurred in Islam in the administration of the sacred law (*shari'ah*) and not in connection with specifically religious functions.

Islam has always been a community under the law as much as a society with a particular religion. Orthodoxy was determined not by councils but by the consensus (*ijmā'*) of the learned doctors (*'ulamā'*) who administered the law within the four interpretative traditions which developed. In the Ottoman Empire, political and religious institutions were one in theory and closely related in fact. Religious functionaries administered education and law, but no autonomous religious organization arose. Distinction between various functionaries never became rigid: the *'ulamā'* were teachers, preachers, legists, and magistrates (*qādī*), sometimes interchanging roles. As payment and pensions were increasingly granted to *'ulamā'* in principal cities, they passed increasingly under centralized executive control. Spiritual affairs, conceived in terms of the sacred law, eventually passed to the supreme jurisdiction of the *mufti* (jurisconsult) of Istanbul, who, as officially appointed head of the leading school of Islamic law, provided legitimation for the sultan's authority (Gibb & Bowen 1950–1957, chapter 9).

But even this development did not provide the basis for an independent religious authority structure. The hereditary principle persisted at the fringe of Islamic social structure, in the ranks of the *Shārif* (supposed descendants of the prophet), and even in the local office of *mufti* (an office unlike that of *qādī* in that it relied on fees for legal consultation and not on a stipend for the discharge of official duties). But since Islam lacked specific priestly functions, the hereditary principle did not bring into being a sacerdotal guild. In all religions, the sacramental element of priestly office appears to be a necessary condition for the development of an independent and centralized religious hierarchy.

In Islam the main factors preventing the development of such a hierarchy appear to have been the restriction which developed on the interpretation of the law; the minimal liturgical character of religious practice and the absence of sacerdotalism; the unrestricted eligibility of all men to perform religious functions; and the establishment of social control through hierarchically organized agents whose functions emphasized the legal rather than the sacred aspects of religiously given law.

### Religious administration and polity

If a founded religion is to survive, it must evolve an organization that will outlast its charismatic founder. Max Weber termed this process "the routinization of charisma." New roles of teacher and legist evolve and are institutionalized. The new functionaries elaborate and codify the prophet's teachings, and priests, if priestly office exists, superintend the development of rituals and liturgies.

**Monks and laymen.** These very general characteristics of founded religions should be borne in mind when we compare East and West. Buddhism, for instance, is vested in a religious order, the members of which neither superintend parishes nor serve congregations. Theravāda Buddhism in its pure form makes few concessions to the laity: the true disciple of the Buddha is not the householder, but the monk. Salvation is remote, and complete renunciation of the world is an ideal practically impossible of attainment. Monks perform ceremonies for laymen, and act as objects of that charity by which laymen can accumulate merit; but the meditation in which, ideally, the monk is engaged is a more meritorious activity. "... The Buddhist clergy are not in charge of the laity. . . . Having retired from the world for self-improvement, the monk expects the layman to come to him" (Wells [1939] 1960, p. 11). The rituals that monks undertake for laymen in Thailand, Ceylon, Burma, and Japan are neither intercessions nor sacramental acts. The hierarchies that have evolved, for example, in Thailand, where Buddhism has been closely associated with the monarchy, are essentially internal to the monastic order itself, even though hierarchs perform state ceremonies (for example, in Thailand), exert political pressure (in Ceylon and Vietnam), or even, as in certain periods in Japan, exercise some political control. In the Theravāda countries, lay Buddhist associations have developed, modeled on Western types of organization and, in Ceylon, directly due to the influence of the Theosophists. In Tibet, where monachistic theocracy developed, and where Tan-

tric magic deeply penetrated Buddhist practice, a religious hierarchy evolved which established lamaism as a distinctive type of Buddhist theocracy. The lamas represented multiple, vicarious, and constantly renewed manifestations of saviorhood in their persons, not by any ordination from above, but by virtue of birth and discovery. Ecclesiastical organization was centered around these manifestations of the Buddhahood, and lamas assumed regulation of the political order. Regulations found in religious writings were intended primarily for monks, and although extended in some measure to the laity, there was no formal code prescribing religious observances for the Tibetan. Monks and lamas did not supervise morals, but offered solace, contact with clairvoyant wisdom, and thaumaturgical power (Ekvall 1964).

**The Christian parish.** In Christianity, bishops divided their dioceses and delegated their sacerdotal authority; thus local units were established, in each of which a priest served the population. Parish organization was the comprehensive territorial provision of religious facilities and religious control. Parochial cures derived from episcopal divine right, and parish priests were supposed to serve all residents in their district, all of whom had religious obligations. The theoretical assumptions implicit in this ecclesiastical organization depended ultimately on the principle of political support for religious monopoly. Parish organization was transformed once the secular authorities permitted religious diversity and even permitted bishops of different churches to claim spiritual jurisdiction over the same territory. Once this occurred, religious movements became voluntary associations on what was effectively a denominational pattern, even though the traditional churches retained the styles and ecclesiastical theories of the older pattern of organization.

**Congregationalism.** Congregational polity rests on different bases of authority—democratic rather than authoritarian and hierarchic. The religious leader is called by the congregation of the self-chosen. He may be accredited by a seminary or by a college of other ministers, but there is always an assumption of spiritual equality among the believers and political equality in the management of their affairs. Furthermore, the laity may assume sufficient knowledge and divine guidance to resist false teaching. Authority beyond the local level may be ill-defined, even in advanced societies with good systems of communication, although local congregations of those who accept a particular theological position are almost everywhere in some form of loose association. Where religious and political institutions are closely associated (as they were in

Islam for much of its history and in seventeenth-century New England Congregationalism), political officials may acquire general superintendence of religious faith and practice.

A necessary condition for congregational autonomy is the absence of sacerdotalism. The religious leader is an administrator, perhaps also a preacher and a pastor. He enjoys neither monopoly nor charisma of office. He may, as in Judaism, acquire enhanced social status by virtue of scholarship or piety, and these may be the demands of the role. All religious roles are achieved rather than ascribed, and there is open recruitment. Where strong differences of education exist between minister and congregation and are reinforced by the establishment of such institutions as seminaries, law schools, and the Islamic divinity school (*madrasah*), tendencies for ministerial and lay expressions of faith to diverge may be noted. If the religion of the learned becomes too intellectual or formal, popular movements, often reasserting the validity of experiential religion, arise in congregational polities as readily as in church organizations (for example, Hassidism in eighteenth-century Judaism and Sufism in Islam). Alternatively, congregational control often diminishes in practice, and an intellectual leadership may introduce new doctrines and liturgies—a process illustrated in the rise of Unitarianism among Presbyterian and Congregationalist ministers in the late eighteenth and early nineteenth centuries.

**Synodical government.** Presbyterianism is a semiconservational polity in which the synodical authority of ministerial and lay representatives at regional and denominational levels is combined with safeguards to preserve some autonomy for local congregations. In the Church of Scotland a complex structure of checks and balances operates to give maximum democratic representation (Highet 1960). A variant pattern of synodical government was forged, though not without schisms, in English Methodism, but with the balance of authority persisting in the denominational conference. Other modern denominations have adopted the same type of system.

**Congregationalism and sacred law.** Congregational polity is legitimated by appeal to Holy Scripture as an objective body of law superior to the authority of institutions—such as the Roman church—which claim a monopoly on scriptural interpretation. Congregational groups usually accept a brief creed stating their understanding of the central teachings and requirements of scripture. This is typical of the Protestant demand for “the priesthood of all believers” (that is, a nonsacramental priesthood)—a demand which relies on

open access to the Scriptures, widespread education, individual right of comment within a broad interpretative framework, and a democratic polity of the kind established by the Congregationalists and Baptists. However, both of these denominations have a professional ministry, in continuity with historic Christian tradition, and this has permitted division of labor and ministerial education, which has grown increasingly specialized. In the absence of a clear authority structure, the professional minister in congregationalist denominations is subject to acute role conflicts and contradictions of status. Clergy role problems are not of course confined to congregational polities, though they appear to be most acute there. Perhaps because this type of ministry is prevalent in the United States these problems have been the subject of numerous sociological investigations (Fichter 1961, chapter 6; Gustafson 1954; Blizzard 1958).

The most radical congregational groups reject a professional ministry, since they believe that any man may minister to others. In the Methodist church, lay ministry became widely established, though it arose from secular democratic pressures rather than in response to a specific theological orientation. It had been developed earlier among the Quakers; it developed as "mutual ministry" among the Disciples; and in some sects, notably the Plymouth Brethren and the Christadelphians, it has been accompanied by a persistent antiprofessionalism.

**Islamic organization.** Islam has always manifested the equality of believers, and any sane male adult may lead others—ideally a quorum of 40—in prayer. In Ottoman Islam, various classes of mosque officials arose in the big mosques; the *imām*, who technically deputized for the caliph, was an *'alim* (learned doctor). With him was often associated a preacher and also a *khatīb*, who delivered two harangues on Fridays; a *mūazzin* to call the faithful to prayer was an indispensable, but usually unpaid, official. The *qādī*, mistaken for a bishop by many Christian writers, administered the *sharī'ah*, and the *muhtasib* served as public censor, ensuring among other duties the maintenance of public morality and the upkeep of the mosque (Levy [1931–1933] 1957, pp. 330 ff.; Gibb & Bowen 1950–1957, pp. 95 ff.). In rural areas today, although the mosque is losing many of its extrareligious functions, it is still the center for ceremonies and charitable activities. Such a mosque usually belongs to the community, but it is the regular attenders who elect elders to look after it. The local *imām* is the spokesman of the *'ulamā'*, but there are no formal channels of communication, and "the various *'ulamā'* neither appoint nor discharge village

*imāms*. This responsibility rests finally with the members of the mosque" (Barclay 1964, p. 165). At village level, the *imām* may get no pay and may have other means of making a living, in much the same way as a parish priest in Greek Orthodoxy. In big city mosques, however, where government or endowment supports religious activities, there is usually a permanent *imām*.

### Religious control of property

Religious organization, even in millenarian sects, involves ownership of property. In the case of Hinduism, the Brahmins initially acted as chaplain-magicians to princes but came increasingly to own, or at least to control, the temples and shrines (Weber 1921). A prebendary system evolved, and members of the priestly class came to acquire property of their own, to which were extended the attributes of sanctity and inalienability. Since Brahmins were a religious stratum and were not hierarchically organized, such property became the property of families or local organizations.

In Western Christianity, by contrast, property came to be owned by a unified church corporation once the Hildebrandine reforms had established a celibate clergy. Indeed, the Roman church, in spite of disendowment in various countries and periods, is one of the largest corporate property owners in the world, even if one leaves out of account its specifically undeployable wealth in the form of church premises and religioartistic assets. This wealth is controlled by specialized agencies which the hierarchy has empowered, and their functions are not open to lay scrutiny. The power of these agencies and the extent to which economic action is dictated by spiritual or political considerations have never been subjected to sociological analysis. The church is a large shareholder in many, especially Italian, enterprises and operates in the capital markets of the world. The invested wealth of the Roman church is thought to be more than \$5,000 million.

The Church of England has assets of about \$560 million; it has entrusted its financial concerns to a body of commissioners, who operate on the stock market in much the same fashion as other investors. The profits from their operation are used partly for subsidization of clerical stipends, which are a more significant issue for the largely non-celibate Anglican clergy than in the Roman church, from whose celibate clergy more complete allegiance can be commanded, and upon whom it can impress more effectively the virtue of frugality. All of the financial operations of the Church of England are open to parliamentary inquiry.

The absence of hierarchy in other religions, and

of a rational financial structure in non-Western societies, has restricted the accumulation of corporate deployable wealth as it has occurred in Christianity, although local religious functionaries have frequently controlled large proportions of local property. Religious premises are often locally controlled, either, as is partially the case in the Church of England, under vested rights of local patrons or through local religious authorities. In the Church of England the right to present priests to "livings" has tended (if we exclude crown and government patronage) to pass increasingly from private to episcopal control (Mayfield 1958; Paul 1964, pp. 195-197). In Islam, local communities are often responsible for mosques, and the local *imām* may persuade regular attenders to undertake repair work on the mosque. The endowment system—a consequence of the emphasis on almsgiving—became extensive in Islam and of such proportions that some governments have maintained special ministries to supervise the *waqf* (endowments) which support mosques, especially in the cities (Guillaume [1954] 1961, pp. 178 ff.; Gibb & Bowen 1950-1957, chapter 12; Smith 1957, p. 205).

Protestantism has usually left control of property to local trustees, but denominational control and the centralization of financial administration have been extended. This appears to have gone furthest in connexional bodies, such as the American Methodist church (Muelder 1963, pp. 148 ff.).

### Church, sect, and denomination

The designation "church" defines an autonomous corporate institution hierarchically organized and served by a professional priesthood. Churches that conform to all these specifications are found only in Christianity; the structural arrangements of other religions are best referred to as religious institutions.

The concept "sect," however, has wider application. In a religion which lacks central organization, members who feel themselves to be religiously deprived and who therefore seek new facilities, new activities, and re-estimations of their social worth can usually be accommodated by the ready accretion of beliefs and practices to the dominant tradition. Only where the social and religious status of established functionaries is threatened are such demands likely to be universally resisted; this may be the occasion for the emergence of a sect—that is, a new religious movement which rejects the authority of the dominant religious tradition.

Although sects arise not only from distinct processes of schism, we may refer to a sect whenever the relations between the new movement and the

one from which it has seceded are characterized by mutual rejection and exclusion (reserving the term cult for movements in which such exclusiveness is absent). This process occurs most typically where the dominant religion is centrally organized. But even in centralized religions, rejection of sectarian elements may occur piecemeal—witness the gradual rejection of Methodism by the Church of England or Methodism's own steady development of sectarian features toward the end of Wesley's life and in the decades following his death. "Sect," then, is a concept of wider applicability than "church," even though the sharpest contrast occurs in the case of Christianity (Troeltsch 1912; Brewer 1952; Wilson 1963).

**Denominationalism.** The sect exists in a relationship of tension with the wider society. Over time this tension may diminish, and as this occurs the sect may evolve into a denomination (Niebuhr 1929). This is by no means an inevitable process; it is true only of certain types of sects and is more conspicuous in the United States than in Europe (Wilson 1959). It has also been maintained (Martin 1962) that not all denominations have evolved from sects. Denominationalism is the typical form of religious organization in the pluralist industrial society. The denomination does not claim universal allegiance coterminous with the state, as does the church; it claims less institutional objectivity. Like a sect, it emphasizes voluntary adherence, but it claims no monopoly of truth and demands much less of its adherents in the way of doctrine or morals. As an institutional form it evidences the diminution and compartmentalization of religious influence in industrial society. Even where it inherits the hierarchic authority structure of the church, it offers more lay opportunity in government. Its religious leadership, in contrast with that of most sects, tends to grow more professional; as Paul M. Harrison (1959) has shown, denominations have a tendency to become bureaucratized.

**Cults.** Denominationalism implies a degree of exclusiveness and inner coherence usually lacking in non-Christian religions. Hinduism gives the individual a choice of cults that emphasize a particular style of devotion to one or another deity (Eliot 1921, chapter 25; Wach 1944, pp. 127-130). Christianity has also evolved devotional cults to particular saints within the Roman church and even personal followings for occasional charismatic individuals, but such movements are more fully coordinated with more regular practices and are subjected to established procedures of discipline and superordinate central authority. Centrally organized, stable movements of a nonexclusive type,

which are, however, more distinctive than church parties, have also arisen in Protestantism: Moral Re-Armament, Anglo-Israelism, and the Faith Mission are examples (Eister 1950; Wilson 1967).

**Monasticism and lay orders.** Monasticism, in which high religious commitment was emphasized by the renunciation of property, sexuality, and personal independence, was the very basis of early Buddhism, and it has been of great importance in Christianity, both under the direction of organized orders in the Roman church and in a more diffuse form in the Orthodox churches. However, it is of reduced significance today. Monasticism, the *collegium pietatis*, and the inner fraternities (for which Wach 1944, pp. 174–186 provides a typology) exist only with the support of the mass of the laity. The maintenance of that support has become an increasing problem for all religions and has tended to direct them from monastic to other patterns of religious commitment. This concern for lay support was, according to Weber ([1921] 1958, pp. 238–240), a principal factor in the transformation of Buddhism from a monastic to a missionary religion.

Among Muslims the development of lay orders (*ṭarīqah*) has demonstrated the need for more immediate allegiances and a stronger emotional orientation than the dominantly legalistic and unritualistic monotheism of the faith provides. Evans-Pritchard (1949, chapters 1–3) sees the Sanusiya in Cyrenaica as a reintegrating agency in an otherwise divisive society. Although the *ṭarīqah* emphasize their orthodoxy, they establish new structural features and superimpose new units of polity, sometimes maintaining their own schools, rituals, and meeting houses. They are not exclusive; members of different *ṭarīqah* may, according to H. B. Barclay (1964, p. 170), pray together in the same mosque, and some men may belong to more than one *ṭarīqah*. Through the lodges (*zawīyah*) new local hierarchies are created, which wield effective power often on the hereditary principle; around this hereditary lineage a cenobitic fraternity arises. The order uses religious feeling as the basis for more dynamic forms of social control. The 'ulamā' themselves became incorporated in the more orthodox orders and this alliance of orthodoxy with Sufism "supplied [it with] a concrete organization which spread over all ranks of society and found a place in it for every member" (Gibb & Bowen 1950–1957, vol. 1, part II, p. 78). The Muslim orders provide an emotional outlet similar to that afforded by the cults of saints which are a widespread accretion to Islam in north Africa (Gellner 1963).

## Religious training and recruitment

The recruitment and training of religious specialists is a field in which very little sociological study has been undertaken. The ascriptive basis of priesthood in traditional Hinduism and Judaism sustained hereditary guilds which monopolized religious functions. Training was thus an apprenticeship in ritual, the mysteries of which were protected by the sanctified social status of its practitioners. In Hinduism the novice was personally subordinated to his teacher's authority. The diversification of Hindu cults and philosophies meant that the postulant for religious experience (usually of a private, ecstatic nature) need no longer be a Brahman but could learn from the *guru* of his choice. Buddhist monks maintain a novitiate with open access and egress; classic Buddhism expects no more of the monastic novice than that he should learn the *dharma*, and accept ten precepts which call for a somewhat more exacting renunciation of worldly attachments than that expected of the laity. The ordained monk rehearses the 227 rules of monastic life. The Buddhist monk of Ceylon and other Theravāda countries is seeking his own salvation, although he does set an example for others and provides them with opportunities of acquiring merit (Ames 1964). He is not a priest, takes no vows, administers no sacraments, and is not prevented from leaving the order at will: "he has no other sanctity than attaches to his own good living" (Coomaraswamy [1916] 1928, pp. 154–155). In Theravāda Buddhism, particularly as it is practiced in Burma and Thailand, it has been usual for boys to spend some time in a monastery as part of their regular education (Eliot [1921] 1954, vol. 3, p. 69; Wells 1939; Nash 1965).

In Christianity, clerical education has evolved along increasingly rational lines, but a sense of vocation (or "calling") is regarded as crucial to occupational selection and training. The Roman church not only stresses the sense of vocation but also presents training for the priesthood as a gradual induction into mysteries which culminates in the acquisition of priestly charisma. Throughout Christianity priesthood is conceived as a lifelong commitment, and ordination is a permanent investment of sacerdotal authority. At the episcopal level, the Roman, Orthodox, Old Catholic, and Anglican churches emphasize apostolic succession. Scholarly education has, however, steadily grown as a requisite of clerical office in Christianity, and there has been, especially in Protestantism, a tendency to reduce the emphasis on the exclusively mystical aspects of clerical func-

tions. As universities have been secularized, clerical education has tended to shift to theological institutions. These are conducted, even within Protestantism, with an intensification of moral rigor that often approaches the monastic, thus achieving a more intense socialization to the clerical role (Fichter 1961). In the Greek Orthodox church only a small percentage of the parish priests have more than a few years of any sort of education, though recently a number of Orthodox seminaries have been established.

### Bureaucratization in the modern church

Administrative centralization has been a conspicuous process in contemporary Christianity. As movements have sought to take advantage of modern techniques and procedures for promoting their mission, they have been obliged to adopt bureaucratic and professionalized organization. The inappropriateness of bureaucracy for the diffuse, affective, and collectivity-oriented values of faith has not prevented its adoption by church organizations (see Etzioni 1961, part I; Paul 1964; Wilson 1965).

The tensions of the situation have been experienced most acutely by those denominations with strong theological dispositions to congregational polity and lay control. Congregationalism itself was basically anticlerical rather than specifically anti-professional, but the shift of decision making from local to denominational level and the development of departmental specialists with far-reaching powers have given rise to fear of a return of an episcopacy. Theological considerations frequently sanctify particular organizational forms or proscribe certain institutional arrangements. This is most evident in the case of sects (Wilson 1967); however, the same dogmatic support underlies church organization, and, though less uncompromisingly, that of denominationalism (see, for instance, Harrison 1959). The analysis of the relationship of ideology and institutional arrangements still awaits the attention of sociologists of religious organization.

## RELIGIOUS SPECIALISTS

- I. ANTHROPOLOGICAL STUDY  
II. SOCIOLOGICAL STUDY

Victor W. Turner  
Ivan A. Vallier

I  
ANTHROPOLOGICAL STUDY

A religious specialist is one who devotes himself to a particular branch of religion or, viewed organizationally, of a religious system. "Religion" is a multivocal term whose range of meanings varies in different social and historical contexts. Never-

theless, most definitions of religion refer to the recognition of a transhuman controlling power that may be either personal or impersonal. A religious specialist has a culturally defined status relevant to this recognition. In societies or contexts where such power is regarded as impersonal, anthropologists customarily describe it as *magic*, and those who manipulate the power are magicians. Wherever power is personalized, as deity, gods, spirits, daemons, genii, ancestral shades, ghosts, or the like, anthropologists speak of *religion*. In reality, religious systems contain both magical and religious beliefs and procedures: in many of them the impersonal transhuman (or mystical, or nonempirical, or supernatural) power is considered to be a devolution of personal power, as in the case of the mystical efficacy or rites established *in illo tempore* by a deity or divinized ancestor.

**Priest and prophet.** Scholars have tended to distinguish between two polarities of religious specialization. Max Weber, for example, although well aware of numerous historical instances of their overlap and interpenetration, contrasts the roles of priest and prophet. He begins by making a preliminary distinction between priest and magician. A priest, he writes, is always associated with "the functioning of a regularly organized and permanent enterprise concerned with influencing the gods—in contrast with the individual and occasional efforts of magicians." Accordingly, the crucial feature of priesthood is that it represents the "specialization of a particular group of persons in the continuous operation of a cultic enterprise, permanently associated with particular norms, places and times, and related to specific social groups." In Weber's view, the prophet is distinguished from the priest by "personal call." The priest's claim to religious authority derives from his service in a sacred tradition; the authority of the prophet is founded on revelation and personal "charisma." This latter term has been variously defined by Weber (in some contexts it seems almost to represent the *Führerprinzip*), but it may broadly be held to designate extraordinary powers. These include, according to Weber, "the capacity to achieve the ecstatic states which are viewed, in accordance with primitive experience, as the preconditions for producing certain effects in meteorology, healing, divination and telepathy." But charisma may be either ascribed or achieved. It may be an inherent faculty ("primary charisma") or it may be "produced artificially in an object or person through some extraordinary means." Charisma may thus be "merited" by fastings, austerities, or other ordeals. Even in such cases, Weber asserts,

there must be some dormant capacity in the persons or objects, some "germ" of extraordinary power, already vested in them. The prophet, then, is a "purely individual bearer of charisma," rather than the representative of a sacred tradition. He produces discontinuity in that cultic enterprise which it is the priest's major role to keep "in continuous operation." Weber's prophet feels that he has a "mission" by virtue of which he "proclaims a religious doctrine or divine commandment." Weber refuses to distinguish sharply between a "renewer of religion" who preaches "an older revelation, actual or suppositious" and a "founder of religion" who claims to bring completely new "deliverances," for, he says, "the two types merge into one another." In Weber's view, the charisma of a prophet appears to contain, in addition to ecstatic and visionary components, a rational component, for he proclaims "a systematic and distinctively religious ethic based upon a consistent and stable doctrine which purports to be a revelation" [(1922); see also CHARISMA and WEBER, MAX].

Weber's distinction between priest and prophet has its main relevance in an analytical frame of reference constructed to consider the relationship between religion as "a force for dynamic social change" and religion as "a reinforcement of the stability of societies" (Parsons 1963). It has been found effective by such anthropologists as Evans-Pritchard (1949; 1956) and Worsley (1957a; 1957b) who are dealing directly with social transitions and "the prophetic break," or what Parsons calls "the primary decision point [between] a direction which makes for a source of evolutionary change in the . . . established or traditional order, and a direction which tends either to reinforce the established order or at least not to change it drastically" (1963, p. xxix in 1964 edition).

**Priest and shaman.** Anthropologists who are less concerned than Weber with the genesis of religions and with internal developments in complex societies or their impact on the "primitive" world are inclined to contrast priest not with prophet but with shaman or spirit medium and to examine the relationship between these statuses as part of the normal working of the religious system in the simpler societies. In their excellently representative *Reader in Comparative Religion* (1958), the editors W. A. Lessa and E. Z. Vogt devote a whole section to this distinction.

Often, where there is a priest the shaman is absent, and vice versa, although both these roles may be found in the same religion, as among the Plains Indians. According to Lowie (1954), a

Plains Indian shaman is a ritual practitioner whose status is acquired through a personal communication from a supernatural being, whereas a priest does not necessarily have a face-to-face relationship with the spirit world but must have competence in conducting ritual. Lessa and Vogt ([1958] 1965, p. 410) expand these differences: a shaman's powers come by "divine stroke," a priest's power is inherited or is derived from the body of codified and standardized ritual knowledge that he learns from older priests and later transmits to successors. They find that shamanism tends to predominate in food-gathering cultures, where the shaman most frequently performs a curing rite for the benefit of one or more patients and within the context of an extended family group. Shamanistic rites are "noncalendrical," or contingent upon occasions of mishap and illness. The priest and priestly cult organization are characteristically found in the more structurally elaborated food-producing—usually agricultural—societies, where the more common ceremonial is a public rite performed for the benefit of a whole village or community. Such rites are often calendrical, or performed at critical points in the ecological cycle.

**Shaman and medium.** Raymond Firth (1964a, p. 638) regards shamanism as itself "that particular form of spirit mediumship in which a specialist (the *shaman*) normally himself a medium, is deemed to exercise developed techniques of control over spirits, sometimes including mastery of spirits believed to be possessing another medium." This definition, like that of Howells (1948), stresses the control exercised over spirits. Howells describes the shaman as "bullyragging" gods or spirits and emphasizes his intellectual qualities as a leader. This element of mastery makes the shaman a distinctive type of spirit medium, one who is believed to be "possessed by a spirit (or closely controlled by a spirit) [and who] can serve as a means of communication between other human beings and the spirit world" (Firth 1964b, p. 689). The spirit medium per se need not exert mastery; he is rather the vessel or vehicle of the transhuman entity.

Thus, although we sometimes find the two functions of priest and shaman combined in the same individual (Piddington 1950), mediums, shamans, and prophets clearly constitute subtypes of a single type of religious functionary. The priest communicates with transhuman entities through ritual that involves cultural objects and activities. The medium, shaman, and prophet communicate in a person-to-person manner: they are in what Buber (1936) would describe as an I-thou relationship with the deities or spirits. The priest, on the other

hand, is in what may be called an I-it relationship with the transhuman. Between the priest and the deity intervenes the institution. Priests may therefore be classified as institutional functionaries in the religious domain, while medium, shaman, and prophet may be regarded as subtypes of inspirational functionaries. This distinction is reflected in characteristically different modes of operation. The priest presides over a rite; the shaman or medium conducts a seance. Symbolic forms associated with these occasions differ correlatively: the symbols of a rite are sensorily perceptible to a congregation and have permanence in that they are culturally transmissible, while those of a seance are mostly in the mind of the entranced functionary as elements of his visions or fantasies and are often generated by and limited to the unique occasion. The inspirational functionary may describe what he has clairvoyantly perceived (or "been shown" as he might put it), but the institutional functionary manipulates symbolic objects with prescribed gestures in full view of this congregation.

**Sociocultural correlates.** Since the priest is an actor in a culturally "scripted" drama, it is but rarely that priests become innovators, or "dramatists." If they do assume this role it is mainly as legislative reformers—by altering the details of liturgical procedure—that they do so. If a priest becomes a radical innovator in religion, he is likely to become a prophet to his followers and a heretic to his former superiors. From the priestly viewpoint it is the office, role, and script that are sacred and "charismatic" and not the incumbent of priestly office. The priest is concerned with the conservation and maintenance of a deposit of beliefs and practices handed down as a sacred trust from the founders of the social or religious system. Since its symbols at the semantic level tend to condense the critical values, norms, and principles of the total cultural system into a few sensorily perceptible representations, the sanctification of these symbols is tantamount to a preservative of the entire culture. What the priest is and does keeps cultural change and individual deviation within narrow limits. But the energy and time of the inspirational functionary is less bound up with the maintenance of the total cultural system. His practice has more of an *ad hoc* flavor; he is more sensitive and responsive than the priest to the private and personal, to the mutable and idiosyncratic. This type of functionary thrives in loosely structured food-gathering cultures, where he deals individually with specific occasions of trouble, or during periods of social turbulence and change, when societal consensus about values is sharply declining and nu-

merically significant classes of persons and social groups are becoming alienated from the orthodox social order. The shaman subtype is completely a part of the cultural system of the food-gatherers; the prophet may well stand outside the cultural system during such a period of decomposition and propose new doctrines, ethics, and even economic values.

The shaman is not a radical or a reformer, since the society he services is traditionally flexible and mobile; the prophet is an innovator and reformer, for he confronts a tightly structured order that is moribund and points the way to religious forms that will either provide an intensified cognitive dynamic for sociocultural change or codify the new moral, ideational, and social structures that have been inarticularly developing.

There are of course significant differences in the scale of the societies in which shaman and prophet operate. The shaman enacts his roles in small-scale, multifunctional communities whose religious life incorporates beliefs in a multitude of deities, daemons, nature spirits, or ancestral shades—societies that Durkheim might have described as possessing mechanical solidarity, low moral density, and segmental organization. The prophet tends to come into his own when the division of labor is critically replacing "mechanical" by "organic" solidarity, when class antagonisms are sharpened, or when small-scale societies are decisively invaded by the powerful personnel, ideas, techniques, and cultural apparatus (including military skills and armaments) of large-scale societies. The shaman deals in a personal and specific way with spirits and lesser deities; the prophet enters into dialogue, on behalf of his whole community, with the Supreme Being or with the major deities of a traditional pantheon, whose tutelary scope embraces large numbers of persons and groups, transcending and transecting their traditional divisions and animosities. Alternatively he communicates with the generalized ancestors or *genii loci*, conceived to be a single anonymous and homogeneous collectivity rather than a structure of known and named shades, each representing a specific segment of society. Whereas the shaman's function is associated with looseness of structure in small-scale societies, the prophet's is linked with loosening of structure in large-scale societies or with incompatibilities of scale in culture-contact situations.

**Divination and religious specialists.** In its strict etymological sense the term "divination" denotes inquiry about future events or matters, hidden or obscure, directed to a deity who, it is believed, will reply through significant tokens. It usually refers

to the process of obtaining knowledge of secret or future things by mechanical means or manipulative techniques—a process which may or may not include invoking the aid of nonempirical (transhuman) persons or powers but does not include the empirical methods of science.

In the analysis of preliterate societies divination often is concerned with the immediate problems and interests of individuals and subgroups and but seldom with the destinies of tribes and nations. It is this specificity and narrowness of reference that primarily distinguishes divination from prophecy. Nadel (1954, p. 64) has called the kind of guidance it offers "mechanical and of a case-to-case kind." The diviner "can discover and disentangle some of the hidden influences which are at work always and everywhere . . . he cannot uncover any more embracing design. . . . Yet within the limits set to it divination has a part to play, providing some of the certainty and guidance required for provident action." Thus, although its range and scope are more circumscribed than those of prophecy, divination is believed to reveal what is hidden and in many cases to forecast events, auspicious and inauspicious.

Divination further refers to the analysis of past events, especially untoward events; this analysis often includes the detection and ascription of guilt with regard to their perpetrators, real or alleged. Where such untoward events are attributed to sorcerers and witches the diviner has great freedom of judgment in detecting and determining guilt. Diviners are frequently consulted by victims' relatives and show intuitive and deductive virtuosity in discovering quarrels and grudges in their clients' kin groups and local communities. Social anthropologists find important clues to areas and sources of social strain and to the character and strength of supportive social norms and values in the diviners' diagnoses.

There is evidence that mediums, shamans, and priests in various cultures have practiced divination. The medium and shaman often divine without mechanical means but with the assistance of a tutelary spirit. In the work of Lessa and Vogt there is a translation of a vivid first-person account by a Zulu informant of a diviner's seance. This mediumistic female diviner

dramatically utilizes some standard procedures of her art—ventriloquism, prior knowledge of the clients, the overhearing of the client's unguarded conversation, and shrewd common sense—to enable her spirits to provide the clients with advice. In this example, . . . a boy is suffering from a convulsive ailment. The spirits discover that an ancestral spirit is spitefully causing

the boy's illness: the spirits decree that the location of the family's village must be moved; a goat must be sacrificed to the ancestor and the goat's bile poured over the boy; the boy must drink *Itongo* medicine. The treatment thus ranges from physical to social actions—from propitiation of wrathful ancestors to prescription of a medicinal potion. (Lessa & Vogt [1958] 1965, p. 340)

Similar accounts of shamanistic divinatory seances have been recorded by anthropologists working among North and South American Indians, Eskimos, and Siberian tribes, in many parts of Africa, and among Afro-Americans.

Divination was a function of members of the priesthood in many of the complex religious systems of Polynesia, west Africa, and ancient Mexico; in the religions of Israel, Greece, Etruria, and Rome; in Babylonia, India, China, Japan, and among the Celts. According to Wach,

The Etruscans made these practices so much a part of their culture that the discipline has been named after them (*disciplina Etrusca* or *auguralis*). Different phenomena and objects were used as media to ascertain the desires of the gods (regular and irregular celestial events, lightning, fire, and earthquakes, the shape or utterances of animals, flights of birds, movements of serpents, barking of dogs, forms of liver or entrails). Both in Etruria and Rome a numerous and well-organized hierarchy of functionaries existed for the practice of the sacred arts. (1958, p. 111 in 1961 edition)

Indeed, diffused through the Roman world, many of these techniques passed into medieval and modern culture.

**Diviner and doctor.** Callaway's account (1868–1870) of the combined divinatory and curative seance in Zululand emphasizes the close relationship believed to hold in many preliterate societies between the functions of divination and therapy. Sometimes, as in the case cited, the diviner and "doctor" are the same person, but more often the roles are specialized and performed by different individuals. Modern therapy is taking increasingly into account the psychosomatic character of many maladies and the importance of sociological factors in their etiology. In most preliterate societies bodily symptoms are regarded as signs that the soul or life principle of the patient is under attack or has been abstracted by spiritual forces or beings. Furthermore, it is widely held that these attacks are motivated by animosities provoked by breaches of cultural, mainly religious, prescriptions and/or by breaches of social norms regarded as binding on members of kin groups or local communities. Thus, to acquire a comprehensive understanding of why and how a patient was afflicted with certain symptoms by a spirit or witch, primitives seek out a

diviner who will disclose the secret antagonisms in social relations or the perhaps unconscious neglect of ritual rules (always a threat to the cultural order) that incited mystical retribution or malice. The diviner is a "diagnostician" who refers his clients to his colleague, the doctor or "therapist." The doctor in question has both shamanistic and priestly attributes. The division of labor which in more complex societies segregates and institutionalizes the functions of priest and medical man has hardly begun to make its influence felt. The diviner-doctor dichotomy does not depend, as does the priest-shaman dichotomy, upon contrasting roles in regard to the transhuman realm but upon different phases in a social process which involves total human phenomena—integral personalities, many psychosomatic complexes, multiple social relationships, and multiform communities.

**Modes of religious specialization.** As the scale and complexity of society increase and the division of labor develops, so too does the degree of religious specialization. This process accompanies a contraction in the domain of religion in social life. As Durkheim stated with typical creative exaggeration in his *Division of Labor in Society* ([1893] 1960, p. 169): "Originally [religion] pervades everything; everything social is religious; the two words are synonymous. Then, little by little, political, economic, scientific functions free themselves from the religious function, constitute themselves apart and take on a more and more acknowledged temporal character."

**Simple societies.** In the simplest societies every adult has some religious functions and the elders have most; as their capacity to hunt or garden wanes, their priestlike role comes into ever greater prominence. Women tend to receive more recognition and scope as religious functionaries than in more developed societies. There is some tendency toward religious specialization in such societies, based on a variety of attributes, such as knowledge of herbalistic lore, skill in leechcraft, the capacity to enter a state of trance or dissociation, and sometimes physical handicap that compels a man or woman to find an alternative means of support to subsistence activities. (I have met several diviners in central Africa with maimed hands or amputated limbs.) But such specialization can hardly be defined, in the majority of cases, as more than part-time or even spare-time specialization. Michael Gelfand's description of the Shona *nganga*, variously translated in the ethnographic literature as "medicine man," "doctor," or "witch doctor," exemplifies the sociocultural situation of similar practitioners in very many preliterate societies (1964).

The Shona *nganga* is at once a herbalist, a medium, and also a diviner who, possessed by a spirit of a dead relative, diagnoses both the cause of illness and of death. Yet, reports Gelfand,

when he is not engaged in his medical practice he leads exactly the same life as the other men of his village. He cultivates his land, looks after his cattle, repairs his huts, makes blankets or other equipment needed by his family. And the same applies to a woman *nganga*, who busies herself with the tasks expected of every Shona woman. . . . The amount the *nganga* does in his village depends, of course, on the demands of his patients, but on the average he has a fair amount of spare time . . . a fair guess would be [that there is a *nganga*] to every 800 to 1,000 persons. . . . The *nganga* is given no special status in his village, his chances of being appointed headman are the same as anyone else's. (1964, pp. 22-23)

*Complex societies.* To bring out best the effects of increase in scale and the division of labor it is necessary to examine religious systems at the opposite end of the gradient of complexity. Religion no longer pervades all social domains; it is limited to its own domain. Furthermore, it has acquired a contractual and associational character; people may choose both the form and extent of their religious participation or may opt out of any affiliation. On the other hand, within each religious group a considerable amount of specialization has taken place. Much of this has been on the organizational level. Processes of bureaucratization, involving rationality in decision making, relative impersonality in social relations, routinization of tasks, and a hierarchy of authority and function, have produced a large number of types, grades, and ranks of religious specialists in all the major religious systems.

For example, the Catholic clerical hierarchy may be considered as (1) the hierarchy of order, whose powers are exercised in worship and in the administration of the sacraments, and (2) as the hierarchy of jurisdiction, whose power is over the members of the church. Within the hierarchy of jurisdiction alone we find such manifold statuses as pope and bishop (which are held to be of divine institution); cardinal, patriarch, exarch, and primate (whose powers are derived by delegation expressed or implied from the holy see); metropolitan and archbishop (who derive their powers from their patriarch, exarch, or primate); archdeacon, vicar general, vicar forane, rural dean, pastor, and rector (who derive their powers from their diocesan bishop).

In addition to the clerical hierarchy there are in the Catholic church numerous institutes of the

religious, that is, societies of men and women approved by ecclesiastical superiors, in which the members in conformity with the special laws of their association take vows, perpetual or temporary, and by this means aspire to religious perfection. This is defined as "the heroic exercise of the virtue of supernatural charity" and is pursued by voluntary maintenance of the vows of poverty, chastity, and obedience, by ascetical practices, through charitable works, such as care of the poor, sick, aged, and mentally handicapped, and by contemplative techniques, such as prayer. Within each religious institution or congregation there is a marked division of function and gradation of office.

Thus there are many differences of religious status, rank, and function in a developed religious system such as the Catholic church. Differences in charismata are also recognized in such terms as "contemplative," "ascetic," "mystic," "preacher," "teacher," "administrator." These gifts may appear in any of the major divisions of the church: among clergy or laity, among hermits, monks, or friars, among female as well as male religious. Certain of these charismata are institutionalized and constitute the devotional pattern particular to certain religious institutions: thus there are "contemplative orders," "friars preachers," and the like.

*Medium-scale societies.* Other developed religions, churches, sects, cults, and religious movements exhibit degrees of bureaucratic organization and specialization of role and function. Between the situational specialization of religious activities found in small-scale societies and the full-time and manifold specialization in large-scale societies falls a wide variety of intermediate types. A characteristic religious dichotomy is found in many of the larger, politically centralized societies of west and east Africa, Asia, Polynesia, and pre-Columbian Central and South America. National and tribal gods are worshiped in the larger towns, and minor deities, daemons, and ancestral shades are venerated in the villages. At the village level we find once more the multifunctional religious practitioner. But where there are national gods there are usually national priests, their official servants, and worship tends to take place in temples or at fixed and elaborate shrines. Parrinder writes:

In the cults of the West African gods [for example, in Dahomey, Yoruba, and Ashanti] there are priests who are highly trained to do their work. These priests are often set aside from birth, or they may be called to the service of the god by being possessed by his spirit. They will then retire from their families and public life, and submit to the training of an older priest. The training normally lasts several years, during which

time the novice has to apply himself to learn all the secrets of consulting and serving the god. The training of a priest is an arduous matter. . . . [He] has to observe chastity and strict taboos of food and actions. He frequently has to sleep on a hard floor, have insufficient food, and learn to bear hardship. He is regarded as married to the god, though later he may take a wife. Like an Indian devotee, he seeks by self-discipline to train himself to hear the voice of his god. He learns the ritual and dances appropriate to the cult, receives instruction in the laws and taboos of the god, and gains some knowledge of magical medicines. (1954, pp. 100-101)

In these west African cults of deities there is a formal division of function between priests and mediums. In general, priests control mediums and carefully regulate their experience of possession. This situation is one solution to the perennial problem posed for priesthoods by what Ronald Knox (1950) has termed "enthusiasm," that is, the notion that one can become possessed by or identified with a god or God and that one's consequent acts and words are divinely inspired, even if they transgress religious or secular laws. In Dahomey, for example (Herskovits 1938), there are communal training centers, called cult houses or "convents," for mediums and assistants to priests. Here the novices are secluded for considerable periods of time. Part of their training involves the attempt to induce the return of the initial spirit possession that marked their calling. They learn later to produce coherent messages in a state of trance. During this period they are under the surveillance of priests. The Catholic church has similarly brought under its control as members of contemplative orders mystics and visionaries who claim "experiential knowledge of God's presence."

**Religious and political specialization.** In many primitive societies an intimate connection exists between religion and politics. If by politics we denote those behavioral processes of resolution of conflict between the common good and the interests of groups by the use of or struggle for power, then religion in such societies is pragmatically connected with the maintenance of those values and norms expressing the common good and preventing the undue exercise of power. In centralized political systems that have kings and chiefs, these dignitaries themselves have priestly functions; in many parts of Africa, for example, they take charge of observances which safeguard many of the basic needs of existence, such as rain making, sowing, and harvest rites, ritual to promote the fertility of men, domestic and wild animals, and so on. On the other hand, even where this is the case, there are frequently other specialized religious functionaries

whose duties are bound up with the office of kingship. An illustration of this occurs among the Bemba of Zambia, where the *Bakabilo*

are in charge of ceremonies at the sacred relic shrines and take possession of the *babanye* when the chief dies. They alone can purify the chief from the defilement of sex intercourse so that he is able to enter his relic shrine and perform the necessary rites there. They are in complete charge of the accession ceremonies of the paramount and the bigger territorial chiefs, and some of their number are described as *bafingo*, or hereditary buriers of the chief. Besides this, each individual *mukabilo* has his own small ritual duty or privilege, such as lighting the sacred fire, or forging the blade of the hoe that is to dig the foundations of the new capital. (Richards 1940, p. 109 in 1955 edition)

The *Bakabilo* constitute a council that exerts a check on the paramount's power, since the members are hereditary officials and cannot be removed at will. They are immune to the paramount's anger and can block the implementation of decisions that they consider to be detrimental to the interests of the Bemba people by refusing to perform the ritual functions that are necessary to the exercise of his office. A priesthood of this type thus forms a constituent part of the interior structure of the government of a primitive state.

In stateless societies in Africa and elsewhere, incumbents of certain ritual positions have similar functions in the maintenance of order and the resolution of conflict. The "leopard-skin chief" or "priest of the earth" (as this specialist has been variously called) among the Nuer of the Nilotic Sudan is a person whose ritual relationship with the earth gives him power to bless or curse, to cleanse a killer from the pollution of bloodshed, and, most important, to perform the rites of reconciliation between persons who are ready to terminate a blood feud. A similar role is performed by the "masters of the fishing spear" among the Dinka and the *tendaanas*, or earth priests, among the Tallensi and their congeners in the northern territories of Ghana. Similar religious functionaries are found in many other regions of Africa. They serve to reduce, if not to resolve, conflict within the society. As against sectional and factional interests they posit the commonweal. In these contexts, moreover, the commonweal is regarded as part of the cosmic order; breach, therefore, is mystically punished. The religious specialists are accorded the function of restoring the right relation that should obtain between society, the cosmos, and the deities or ancestral shades.

## II

## SOCIOLOGICAL STUDY

A religious specialist is a person in possession of ritual authority, esoteric knowledge, or spiritual gifts who is recognized as competent in the solution of religious needs. These needs may emerge from a demand for services on the part of a local group, from the exigencies of an organized cult, or from the political requirements of a ruling elite. The shaman witch doctor among the Ostyaks, the Brazilian Bororos, or the early American tribesmen is, from this perspective, as much a religious specialist as the Brahman priest or the Jewish rabbi.

Modern industrial societies, distinguished by cultural pluralism, status mobility, and rigorous performance standards, generate a wide range of religious needs and, thereby, divergent lines of religious specialization. Yet, in broad terms, religious specialization takes place within two spheres: within the professional clergy, who constitute the specialists for the organized religious bodies; and within the residual category of the grass-roots, client-oriented practitioners. Members of this latter category, including faith healers, clairvoyants, mediums, and self-styled prophets, acquire leadership and influence by their capacities to identify, articulate, and relieve spiritual problems. These practitioners, with local followings and *ad hoc* ritual techniques, occupy a distinct place in the realm of religious leadership today and wield considerable influence among the dispossessed who live outside the central orbit of middle-class life.

The professional clergy constitute an important subcategory of modern religious specialization. In turn, the term "clergy" bears two connotations—one technical and limited, the other descriptive and sociological. In the first sense, "clergy" (derived from the Greek term *kleros*, meaning "lot" or "portion") refers to the ordained ministers of the Christian religion. Inherent in this definition is the ritually conferred status of authority and responsibility in relation to a body of believers, or the laity. Within Roman Catholicism the clergy make up the major orders, with three canonically defined ranks: bishop, priest, and deacon. Priests, in turn, are either religious or diocesan (secular); the former live in a community under rule, whereas the latter work under the diocesan bishop as parish priests, attending to the care of souls. Protestant groups equate "clergy" with "minister," emphasizing the role of servitor, as opposed to the Roman Catholics, who place emphasis on sacramental function (Knox 1956, pp. 1-3). In the churches of the Anglican

Communion, however, the Roman Catholic terminology is generally applied (Hardy 1956, pp. 150–155). Hence, the connotation of a consecrated full-time professional leader is applicable throughout Christianity, even though differences are recognized according to tradition and theological position. Informal terms are also used to identify levels and types of Christian clergy: “higher” and “lower” clergy, terms used in the Eastern Orthodox church in prerevolutionary Russia; the “foreign” and the “indigenous” clergy, terms developing out of the missionary situation over the past century; “established” and “free” clergy, terms frequently used in countries like England and Sweden, where a state religion with a salaried clergy coincides with a nonconformist tradition. Characteristic divisions are made in terms of sexual status or family involvement—the celibate versus the married—and in terms of function—the curate, the priest, the preacher, the evangelist, the administrator, the therapist.

The second, more general use of the term “clergy” is increasingly employed by social scientists, journalists, and comparative historians to refer to all types of sacred experts. In this sense, the term identifies any full-time functionary connected with one of the major world religions. On this level, “the clergy” indicates a professional stratum or occupational group in society. “The American clergy” is a social category that automatically includes Protestant, Roman Catholic, Eastern Orthodox, and Jewish leaders.

Variations in the directions and types of specialization by function provide crosscutting bases for classification that cover both the professional clergy and folk experts. The roles of rabbi, the Islamic ulema, and the Roman Catholic canon jurist are specialties developed in connection with the interpretation of religious codes, holy laws, and ecclesiastical rules. Roles dealing with problems of illness within a religious framework include that of the exorcist, the pastoral counselor, and the Christian Science practitioner. Denominational officials, district superintendents, and seminary presidents hold key administrative-supervisory positions. Whether or not these same distinctions warrant inferences about elite status depends on the particular sociopolitical context.

### Classic studies of religion

Certain substantive issues, including priestly division of labor, sequential developments of religious types, and the functions of religious specialists in group life, have taken on special importance

in scholarly interests over the past hundred years. The discipline of comparative religion, launched in the mid-nineteenth century by philologists, historians, and students of mythology, produced a rich deposit of descriptive materials on the religions of ancient civilizations, including Babylonia, Egypt, Israel, China, Greece, and India. Although these scholars concentrated primarily on beliefs, attributes of deities, and ritual practices, they also contributed abundant information on priesthoods and other types of religious specialties, as well as the dynamics of priestly power and political change. However, this phase of early research, while still valuable, did not yield analytical arguments or explanatory theories regarding religious specialization.

The social evolutionists went to the other extreme. All types of religious and social phenomena were scrutinized and ordered into developmental phases, and speculative theory took precedence over comprehensive description. This enterprise made three contributions to the topic of religious leadership: the correlation of religious leadership forms with stages of cultural growth; the analysis of the role of psychological factors in the achievement of superior religious status; and the description of evolutionary development of specific religious types, with particular attention to the transition from the magician to the priest. Comte's work, although infused with the subjective optimism of the nineteenth-century positivists, connects evolutionary theory with the conditions for the rise of priesthood and its role in stabilizing the so-called theological stage of civilization.

The originators of the functional approach to religion and society—Robertson Smith, Émile Durkheim, Bronislaw Malinowski—did not identify religious leadership as a distinct theoretical problem, although a series of new concepts and generalizations on this category of specialization emerged indirectly from their work. Centering their primary attention on the universal properties of religion as a social phenomenon and its role in fastening group needs to the moral order, the functionalists considered ceremonial leaders and priestly activities secondary to religion as a key subsystem. In their dissatisfaction with earlier rationalistic and psychological views, these functionalists tried to demonstrate that religion is a distinct category of social experience; that it develops significant interdependencies with other institutional realms; and that it plays an undisputed function in society's operation and development. The combination of this broad theoretical polemic with their reliance

on materials from early and preliterate societies thereby led them to de-emphasize questions having to do with the internal differentiation of religious systems and the specifics of varying lines of ritual activity.

Freud's work holds a particular place in the intellectual development of this field. His theory of religion had three emphases: the origins of religion, centering around totemism; the psychological and cultural determinants of religious leadership; and the functions of religious action and beliefs for the personality system. Freud defined religion as a group neurosis—a fixation stemming from unresolved infantile conflicts that originate in early relationships with the parents, especially the father. The priest or religious leader serves as a surrogate parent, allowing for the neurotic expression of adult dependency needs but at the same time creating an unconscious ambivalence controlled through the observance of taboos. Furthermore, the presence of the religious leader re-creates the bonds of pseudo familism between member and member, as well as between member and leader. Although Freud provided a theoretical explanation for the emergence and persistence of religious leadership as a universal, he made no attempt to account for the development of special types of religious roles or to explain differences and variations from one society to another.

Max Weber provided the necessary breakthrough from historical-descriptive investigation and evolutionary theory. His comparative study of world religions, which focused on a theory of religious ideas and economic change, brought attention directly to religious functionaries as agents of social transformation or as conservators of tradition (Weber 1922). Priestly activity, historically combining with prophetic developments, produces a progressive "rationalization" of religious ideas. Weber saw these systematic orderings of supernatural conceptions as critical for levering men away from traditional, magical, and undifferentiated religious world views; hence he viewed the priesthood as a powerful educating force, which mediates between a world of magic and a world of ethical rationality. Utilizing the evolutionary technique, Weber delineated the development of various forms of religious specialization in sequences representing magician, mystagogue, and priest. Moreover, he compared the conditions under which different types emerge—prophet, lawgiver, teacher, or contemplative mystic—and went on to trace the economic, intellectual and political consequences of these various types of leadership and authority.

### Contemporary research

Since 1920 studies of religious specialists have moved away from the classic preoccupations with typologies and evolutionary sequences to one or another of the following problem areas: the clergy's personal and social characteristics, with emphasis on origins, recruitment factors, theological and political attitudes, and conceptions of their status (for example, Donovan 1958; Smith & Sjöberg 1961); the institutional context of clergy behavior and performance built around concepts derived from role theory and occupational issues, thus stressing status dilemmas, role strains, career lines, and the clergy's mode of integration with other professionals and clients in special settings, such as therapy networks and chaplaincies (Fichter 1954; Blizzard 1956; Cumming & Harrington 1963); broad diagnostic analyses of the clergy as a modern profession, with particular attention to the declining role of the sacred in industrial-urban life, the special criteria underlying the clergy's claim to professional status, and the sources of the clergy's alienation in the contemporary world (Hagstrom 1957; Fichter 1961; Gustafson 1963); and finally, comparative investigations of the clergy as members of local and national elite power structures, including their place among community influentials and as agents of change or tradition in the developing countries (Form & D'Antonio 1959; Underwood 1957; Pope 1942).

**Recruitment of religious specialists.** Clerical recruitment receives special attention from researchers because of the traditional religious leader's strategic role in communal life and his association with privilege, prestige, and even wealth. Criteria of eligibility for these elite positions are usually distinctive. Cross-culturally, the prerequisites range from physical fitness and extraordinary psychic capacities to hereditary status, sex, age, and spiritual experience. In the modern societies of the West, first attention is given to qualifications based on formal training, to the candidate's conviction of having received a "call," or to the seminary professors' judgments about the future clergyman's social skills, his psychological stability, his strength of professional commitment and, if he is Protestant or Jew and married, to the suitability of his wife for the pastoral situation. Contrasts in recruitment criteria are frequently overemphasized, to the neglect of examining the criteria's implications for other issues, such as the relationship between supply and demand.

Determination of eligibility by birth, which pro-

vides candidates without reference to need, may lead to oversupply. In the interest of making use of these resources, the division of labor involved in ritual is sometimes elaborated, allowing for the participation of greater numbers; such appears to be the case in Hinduism, where sacrifice requires the attendance of six or seven Brahman priests. Hereditary rights to sacred privilege thereby create vested interests in achieving and maintaining full ritual employment. However, different factors work to curtail this kind of elaboration. For example, believers can refuse to support additional religious leaders or turn to less costly substitute functionaries. The establishment of a centrally controlled ritual altar also reduces opportunities for leadership; thus members of the local hereditary priestly groups in ancient Israel lost their positions when sacrifice was limited to the temple in Jerusalem. In contemporary India, priestly Lingayat lineages solve the problem of oversupply by dividing the ritual role among the eligible by a process of rotation, each man holding the position of priest for one year in eight or ten.

Shortage, however, is a more serious problem than oversupply. As established sources decline or as emerging needs require additional recruits, religious bodies are forced to devise new recruitment strategies. Shortage problems of this kind are more characteristic of universalistic, missionary religions of the West, where the religious professions are of relatively low prestige, while the core spiritual functions remain the prerogative of an ordained elite. Roman Catholicism is often confronted with a particularly difficult dilemma in this respect: since salvation is dependent on the sacraments, and their administration is largely confined to the priest, large memberships in strategic regions are often without adequate pastoral care. This pattern is today particularly conspicuous in Latin America, where shortages of clergy reach crisis proportions. Not only is it common to have one priest for eight to ten thousand members, but the laity may be so distributed geographically as to make regular services impossible (Alonso et al. 1962; Pérez & Wust 1961). In order to mitigate the shortage, priests are being transferred from other nations, laity roles have been heightened, and the diaconate is being re-established as a part of the orders. Protestant bodies in Great Britain and the United States today also face problems of shortage. Particular concern is shown in the United States for recruiting clergy who know and understand urban issues. Most ministers are drawn from towns and small cities; yet the crux of contemporary Protestantism's problem

lies in developing influence in urban areas. Hence, the issue of a shortage of clergy is complicated by the issue of cultural background. Furthermore, while the need for clerical strength increases, the secular professions steadily offer wider opportunities and higher material rewards for college graduates. This intersection of rising demands and lowered supply places the churches in a double bind, with no immediate amelioration in sight.

**Training of religious specialists.** The variations found in procedures for training the clergy and other religious specialists are striking and may be viewed in terms of structural context, content, and duration. The principal differences in structural context are made plain by contrasting the father-son pattern that is found among traditional priestly family groups with the autonomous, interdenominational, university-affiliated seminaries that provide training for future ministers in the major American Protestant denominations. Between these two poles fall the teacher-disciple relationship, the work of seminaries sponsored and controlled by particular religious bodies, and the special schooling required for candidates to the religious orders and religious congregations. In the early Roman Catholic church, priests were trained in cathedral schools, which generally gave way to the universities in the twelfth and thirteenth centuries. The Council of Trent in the sixteenth century established the requirement of seminary training. Prior to the 1917 revolution, Russian clergy of the Eastern Orthodox church were trained in seminaries, but there were only one or two of these, and most of the lower clergy were not trained at all. The center of scholarly training for the Islamic ulema is al-Azhar in Cairo; however, throughout most of the world, training in the Koran is carried out by local teachers, who pass the tradition on to students. In the United States the need for additional Protestant preachers and ministers in the eighteenth and nineteenth centuries led to the founding of numerous religious colleges. Moreover, an increase in the demand for licensed clergy in modern times has created a flock of diploma mills and pseudo seminaries.

Training does not always prepare religious specialists for their work. Because this holds true for the major Christian bodies today, a critical evaluation of the seminary and its curriculum is taking place. The clergy are disciplined in church history, theology, and dogma only to find that the pastoral role demands administrative capabilities, human relations skills, practical techniques in the programming of secular activities, and the ability to eval-

uate and act in relation to community needs. This confusion between professional expectations and professional realities is held to be the key source of low morale and insecurity among the clergy (Niebuhr 1956).

**Career mobility.** Religious specialists are career men in that their commitment to the sacred office is usually for life. Thus, patterns of placement and tenure are understandably important. Many Anglican clergymen, for example, hold beneficed positions from the time of their ordination until their death. This tenure system has many drawbacks, not the least being the episcopate's loss of control over the lower clergy. The Roman Catholic secular priest is usually assigned in the diocese within which he has received seminary training. In the congregationally centered Protestant denominations, the ordained minister is contracted for by the local church, though frequently on the basis of recommendations from denominational officials. This same policy holds in Conservative Judaism. Procedures of appointment, whether from above or below, affect the clergyman's mobility and his conceptions of success. In the congregational churches, ministers move frequently and widely. Competition is keen for the best churches.

Barriers to advancement are of many types, including particularistic preferences for manner or speech as well as slow turnover at the top levels. The growth of administrative positions and the opening of special ministries in the big cities are helping to relieve some of these mobility pressures. When openings do exist, the criteria for promotion are often unclear. The close involvement of the clergy in ritual duties, symbolic acts, and ministries of love complicates the whole process of evaluation. Lacking explicit criteria for judging clerical performance, many religions fall back on the seniority principle. The clustering of the older men at the top tends, of course, to increase the inflexibility and conservatism that are often associated with religious organizations. Although the clergyman's position in society is a secure one, the internal pattern of his professional success often depends on skillful maneuvering and patience rather than on accomplished performance. In particular cases success is not anticipated, at least not in terms of moving up. The lower clergy in the Russian church before the Revolution were prohibited from receiving appointments to vacant sees, both because they were married and because they were socially inferior. This barrier between the church's higher offices and the local clergy has been maintained throughout most of the past four hundred years in Latin America.

**Political position of the religious elite.** The potential conflict between priests and rulers, or between religious and secular elites, erupts from various causes, revealing itself in at least three situations: when sacred principles are used to challenge the legitimacy of political authority, as most clearly exemplified in the contest between *regnum* and *sacerdotium* in western Europe from the eleventh to the fourteenth century (Parker 1955); when religious leaders gain a monopoly over a sector of public life that is deemed essential to the development of society, as was the case in the conflict that emerged in France during the 1880s over the secularization of the schools (Moody et al. 1953); and when religious leaders or sacred authorities initiate programs that violate moral sensibilities or secular law, for example, the Mormons' practice of polygamy in the United States after their move to Utah. Conflict is least likely when the religious cult is controlled by the government, with the priests serving as official bureaucrats, and when, as in classical China, the state officials perform the ritual ceremonies. The complete separation of church and state is an equally stable solution, demonstrated by the history of the United States over the past 180 years.

The social strata from which the clergy are drawn is another relevant factor. If they are identified with a single class, as in prerevolutionary France, hostilities toward the clergy may polarize, drawing power from general social antagonisms. When, on the other hand, clergy are drawn from all classes, class hatred is potentially reduced, since every family or status group has a clerical representative. Religious elites gain adaptive advantages from other sources, including their capacity to draw personnel and finances from other countries—as in present-day Roman Catholicism—their possession of publishing houses and parochial schools, and the extent to which the religious system is centralized, allowing control over the movement and allocation of religious specialists.

Over a period of time, the position a religious elite holds in the political sphere may change because of changes in the elite's function and its relationship to levels of social structure. In the United States the power of the clergy on the community level is changing from that of decision maker to that of an agency for mobilizing support on issues already decided. Among the clergy in France, emphasis has moved away from competing for formal power on the national level toward the promoting of value change in local settings. In all modern industrial societies, the trend of the clergy is away from open political struggle and toward a

reliance on their religious authority to influence issues that are held to be of moral and social importance. In broad terms, the change is from open, direct maneuvers to indirect persuasion and suggestion, frequently backed up by joint statements that crosscut denominational and faith lines.

**Internal conflict.** Although overtly symbolizing solidarity and stability, religious elites are frequently divided by internal strife and competition. In the present era new factors are emerging to foment such differences. Developments in Protestant groups at the level of central administration, with their attendant changes in authority and power, infringe on the autonomy of the local pastors. Ecumenical moves and cross-denominational cooperation are stimulating reactions among clergy who take historical differences seriously. In another dimension, the problem of defining the mission of the church in society provides room for varied concepts and sharply defined differences of opinion: some groups see the church as an agency of social reform, whereas others view the congregational unit as a center of religious fellowship, ritual worship, and inwardly focused spirituality. Roman Catholic divisions today center less on matters of belief and dogma than on conceptions of the church in relation to society and on the nature of authority and its appropriate means of institutionalization. The major issues in these debates center on the opposition between the ascetic view of the church and the view emphasizing the church incarnate; between the conservative view of priestly authority and the view favoring lay-clergy cooperation; between bishops favoring the supremacy of the pope and those holding for increased decentralization; and finally, between those regarding religious orders as fortresses of spiritual contemplation and those desiring their increased role in the active apostolate.

**Religious leaders and the laity.** Many of the vital issues underlying the problems and dilemmas of religious leaders emerge in the relationship of the clergy to laymen. In the past, conflicts between laymen and clergy were embodied in the laity's rebellion against sacred privilege, lax morality among priests, the economic burden of church taxes, and the methods of clerical appointment. Different problems have emerged in the modern period to foster clergy-laity tensions. The enormous rise in educational level of church members in Europe and the United States robs the religious leader of his earlier position as a man of learning; at the same time, the laity demand more from him as minister, social leader, and administrator. Matters of control over ecclesiastical property and ap-

pointment prerogatives are now less central, in most instances, than that of the social relationship between the pastor and his charges. Although the norms governing this basic relationship are in a process of change, they tend to give priority to expectations of warmth, personalism, and service. The full-time religious leader is expected to live up to these norms and to be accessible and available at all times. The core problem that emerges from this typical situation has its source in the religious leader's struggle to maintain effective distance from the demands and invitations that laymen consider appropriate. Various arrangements help to offset these difficulties: closed residence for priests; location of the minister's home at a distance from the house of worship; segregated religious assemblies, such as special retreats for religious leaders; distinctions in dress; and limitation of contact to ritual occasions or to special appointment hours. Centralized religions often follow a policy of periodically reassigning their local leaders, thereby indirectly reducing patterns of long-term involvement between leader and membership.

A distinctive and growing source of clergy-laity conflict is in evidence in the contemporary Roman Catholic church. The movement toward increased lay participation, initiated by Leo XIII in the last decades of the nineteenth century, has gradually taken root in France, Belgium, the United States, Brazil, and Chile. For the past seventy years the church has tried to reach alienated membership groups, ranging from the French urban proletariat to the Chilean rural peasantry. This ambitious undertaking places an enormous strain on church labor reserves, and local clergy are inadequate to carry out this new responsibility. The laity has therefore become a potential auxiliary work force, assuming organizational assignments such as teaching the catechism, actively proselytizing, organizing youth groups, and assisting with the administration of the sacraments (Marie Joseph 1953). These changes provoke tensions between the diocesan clergy and the laity, since the clergy's power and prestige tend to decline, while the status of the layman rises. Thus, the membership both expect and demand greater voice in local church administration and policy decisions. It is clear that the priest's "charisma" of office is no longer an adequate basis for his authority. He must be knowledgeable as well as schooled, and the power of his leadership increasingly rests on his spiritual-social qualities rather than on the symbolic duties of the sacramental role.

**Religious elites and the social order.** A view of the broader role the clergy play in society under-

lines other aspects of religious leadership's complex nature. Except for some monastic communities and certain types of professional mystic, sacred men are always intimately bound up with the wider social order. The over-all trend of the clergy's place in society is that of narrowed functional importance, while the trend within the religious unit is toward increased scope of functional responsibility. A recognition of this dual change helps explain many of the current findings relative to the clergyman's confusion and insecurity. The interpretation that some sociologists give to the "minister's dilemma" holds that added administrative and social responsibilities in the local church have created strains in carrying out the roles of pastor, preacher, and ritual agent. Hence, multiple roles are taken as the cause of the clergyman's distress (Blizzard 1956; Fichter 1954).

This explanation is unsatisfactory, since it fails to take account of the changing place of the religious leader in society. The clergyman has often filled multiple roles. In seventeenth-century England, for example, the local clergyman served as lawyer, teacher, counselor, doctor, and community social leader, as well as preacher and administrator of the sacraments; his time and energies were more in demand than those of his modern counterpart. However, the important fact is that these multiple roles brought status and respect from society: he was visible, needed, and rewarded. Today the clergyman still finds himself with multiple roles, but they are bound up with the internal activities of the religious unit. The organized religions are now confronted with the painful problem of re-establishing a position of usefulness and influence in society. Organizational activities thereby assume strategic importance, as a means of attracting people and as a way of increasing leadership effectiveness. In this situation the local clergyman is pushed to become planner, strategist, organizer, and action leader. These demands, however, arise from within the religious system, not from society. He is thereby separated in his work from the eye of the public, the major spheres of social reward, and the growing prestige of the secular professions; yet he is expected to meet the requirements of a demanding position.

### The clergy and social change

Controversy continues to surround the clergy's relationship to social change. Priestly professions and conservatism often go hand in hand. At least three factors play a decisive role in building this conservatism: high priests and religious officials are often recruited from society's upper strata; re-

ligious beliefs characteristically stress otherworldly rewards, thus devaluating secular progress and accomplishment; and ritual exactness and adherence to form are assumed to hold a central role in maintaining the benefits and favors of supernatural entities. Thus, tampering with time-honored techniques may disturb an established positive balance. Certain conceptual refinements, as well as changing social conditions, serve to qualify this static picture. For example, typologies applicable to religious roles—such as "priest" versus "prophet," "pastor" versus "administrator," or "local" versus "cosmopolitan"—provide useful distinctions between specialists who focus on religion's conserving functions and those who attempt to create new breakthroughs in religious meaning, action, and organization (Wach 1944). Modern theologians symbolize this innovative side.

Moreover, within a given type of religious specialty or within a historical period, the institutional context of the specialist's work must be taken into account. Clergymen who are assigned duties outside the denominational-parish context are often more committed to innovation and change than their secular counterparts. With the proliferation of special ministries, including factory programs, university and hospital chaplaincies, and inner-city missions, a growing number of clergy are partly freed from traditional authority and conformity-based parish pressures. However, these new men are vulnerable to other pressures, which emerge in the outside settings, as the "worker priest" experiment showed (Edwards 1961; Poulat 1965). Ministers who lead local congregations, on the other hand, are tied directly to a traditionally defined religious unit, from which they draw their rewards. Their stand on a moral or sociopolitical issue—whether civil rights, ecumenicism, or federal aid to education—depends on the values of the dominant lay groups. Conservatism or its opposite therefore tends to be built into the situation. Present-day critics of the Southern clergy's reluctance to lead out for racial integration overlook this intimate relationship between context and behavior (Campbell & Pettigrew 1959).

Recent empirical studies suggest that the clergyman's effectiveness as a counselor, or as an agent of personality change, is also limited by this tie-in with a concrete religious group (Cumming & Harrington 1963). Although he is accessible, shares key values with his parishioners, and is often well prepared to understand the depth factors that produce personal stress, he lacks the professional distance of the psychiatrist or caseworker. Two consequences flow from this situation. First, though

the clergyman is frequently consulted before any other professional by members of his congregation with personal problems, the relationship with the "patient" is usually weak or easily interrupted. Members tend to withhold information, fearing that it may get "loose in the system," or they withdraw from the relationship altogether. Second, the clergy's identification with a religious tradition leads other professionals who give counsel or therapy (psychiatrist, social worker, doctor) to overlook the local clergyman as a member of the broader deviance-control system. Even when a patient's problem appears to warrant "religious counseling," referral to a minister is seldom made; yet the clergy steadily refer members of their congregation to secular professionals. Thus, the clergyman in his role as therapist gives more than he gets, not simply because he is less qualified but also because he is viewed by his secular colleagues in the community as an agent of a particular belief system, and more broadly, as a man with a "moral outlook."

The overseas missionary, also, is a distinct type of religious specialist. This fact calls for some extension of these qualifications about the clergy's role in social change. The clergy's fostering of schools, hospitals, agricultural technology, and programs of community development in Asia, Africa, and Latin America represents a major type of directed change (Maddox 1956). In fact, the missionary led the way in various types of socioeconomic reform throughout these areas, between the late nineteenth century and the end of World War II. Since 1945 government technical missions, United Nations teams, and special overseas programs, such as the Peace Corps, have largely eclipsed the missionary's frontier role in promoting change. Moreover, the implicit association often made between foreign missions and colonial interests has further reduced missionary opportunities. Paralleling these developments, leaders of the organized religions increasingly recognize that church survival and growth depend not only on overseas work but also on new types of entrepreneurship on the domestic front, especially in the metropolitan areas and among workers and racial and ethnic minorities. In those remaining areas where proselyting is permitted, foreign missionaries also confront growing pressures to turn their work over to an indigenous clergy. The Catholics appear to be more successful in this grass-roots endeavor than the Protestants, partly, of course, because of differences in administrative and financial policies.

The role of religious leadership in social change is further clarified by taking account of the re-

ligious system's authority structure. Centralized, hierarchically organized priesthoods frequently breed divisions of a "higher" and "lower" order, the latter stratum being held in subservience by the superiors. Tensions that emerge from this caste-like pattern are available for displacement into political directions during periods of social unrest, the lower clergy uniting with other oppressed groups as supporters of the liberal cause. This happened in Latin America from 1810 to 1830, and in Russia following the 1917 revolution. Hence, both tensions within religious leadership groups and conflict among religious elites may help foment social change and liberal activity, depending on how these antagonisms become fused with broader political and economic forces. In contemporary Latin America, especially in Chile and Brazil, the Roman Catholic clergy are demonstrating an unusually progressive position on social change (Vallier 1965). This is a surprise, considering the historical position of the church in these areas. Further examination reveals, however, that in both Chile and Brazil secular and religious threats are very real, one source being the radical political doctrines of the socialist and communist left, and the other the successes of the Protestant sects. Liberal steps, such as the distribution of church lands to peasants, the establishment of technical-training schools, and trade-union activity, are seen as new ways of capturing religious loyalties. Hence, to understand the position that priests or ministers take in fomenting or restricting social change, a whole range of referents need to be specified.

**New patterns of religious specialization.** Viewed from within the broader context of the modern professions, religious specialization in Christianity exhibits several noteworthy patterns. As in medicine, law, and university teaching, growing lines of differentiation (therapy, social research, ecumenicism, liturgy, and domestic missions) create pressures for integrative-coordinative roles. Thus, experts in administration, communication, and planning gain visibility and influence. In American Protestant denominations these coordinative problems loom very large, and internal power struggles increasingly emerge around these units. American Roman Catholicism, on the other hand, is well-developed as an administrative and policy-making body but lacks effective lines of specialization with respect to problems of the laity, interfaith cooperation, and the linking of group worship to communal forms other than those resulting from traditional ethnic bonds. In Europe the dominant line of specialization is the theologian's role within the realm of Judaeo-Christian ideas as a culture; theo-

logical activity is heavily linked to Biblical studies—a combination that is producing a major creative thrust. The core problems for European Christianity emerge at the level of meaning and ideology rather than in the spheres of organization and action. Thus, possibilities for the development of Christianity hinge on the theologians' capacities to establish competitive systems of faith vis-à-vis Marxism, existentialism, and secular totalitarian mystiques. In broad terms, lines of religious specialization differ not only by Protestant and Catholic traditions but also by continents.

### Directions of research

From the foregoing considerations, it is clear that the subject of modern religious specialists comprises diverse substantive problems and important analytical issues. Religious specialists not only continue to hold a distinctive place in the contemporary world but also make up a key category in the study of occupations, social movements, culture, and organization. Yet this field presently lacks vitality and direction within the social sciences. New evaluations are needed to restore to it some of the contributory capacity it earlier possessed. Several suggestions are in order.

One possibility is to connect the study of religious specialization more fully to the problem of the churches' ambitions to retain and extend forms of religious influence in modern society. Both Christian and non-Christian groups seek to maximize their spheres of dominance, and in these endeavors traditional strategies and former linkages with the social order lose importance. Consequently, innovation, entrepreneurship, and institution building, as instruments of religious influence, are highly significant and thus become points of structural growth and change. Comparisons are possible between major religious traditions—Christianity, Judaism, Islam, Buddhism, and Hinduism—and within distinct faiths (Vallier 1962). The three great modern adaptations of Roman Catholicism—in western Europe, the United States, and Latin America—constitute only one subspecies within which religious specialization and the problem of achieving new lines of religious control could be studied. The point, of course, is that religious specialists should be viewed as more than members of an isolated occupational category or local leaders frustrated by new pressures. An approach that focuses on patterns of specialization in relation to the evolution and change of total religious systems would be more fruitful.

A second possibility involves the comparative study of religious specialists as factions within a religion's "political" subsystem. Although conflicts

and power struggles are endemic to all religions, these divisions are too often examined within the limited "liberal" and "conservative" categories. This is a risky oversimplification. The liberal Roman Catholic development in modern Europe or in Latin America is actually made up of diverse interests, orientations, and ideologies, each with its own elite and identity. In this same sense the Roman Catholic hierarchy of the United States is often labeled "conservative" relative to the liberal groups in Europe. However, no one would seriously argue that the conservative elite in the American hierarchy hold the same views and positions as the Italian prelates who control the Curia. Liberal Protestant clergy are often lumped together by such flimsy criteria as their attitudes toward the Bible or their reading of the *Christian Century*, but again the spectrum is very wide. Moreover, to identify a segment that holds similar attitudes does not allow any inference about the role these individuals play in the internal political arena. In addition to the need for work on intrareligious conflicts and factions, further extensions are appropriate for systematically relating religious elites to nonreligious elites in the wider context of modern society. Studies of community power structures provide suggestive leads for this problem.

Other possibilities are open for developing the subject of religious leadership. The traditional emphasis on typological diversity tends to obscure the central question as to what sacred positions have in common. Distinctions by rank, function, and training are often taken to be more important than the characteristics that religious specialists share as a distinct category of social structure. The simple fact that all religious specialists are focused primarily on the realm of the nonempirical and religioethical absolutes sets them apart from statesmen, business executives, and doctors. The clergyman lacks a technical body of knowledge that can be applied to the solution of empirical problems. In that sense he cannot practice his profession; instead he must live it. For the most part, his base of knowledge is normative and closed rather than scientific and open. He interprets, while his colleagues in the secular professions prescribe; he tries to give meaning to the event, since he cannot control it. Thus, to place the clergy along with lawyers, academicians, social workers, and engineers into one broad category marked "professionals" is to violate several distinctives of singular theoretical importance. As the special properties of sacred elites become clarified, knowledge of religious dynamics and of the nature of the professions will be advanced.

## RENT

There are at least three distinct classes of meanings for *rent*: the common usage, the usage in classical economics, and the usage in modern economics. These are discussed in turn in this section. More restrictive meanings or special kinds of rent will be discussed under the appropriate general classification. In succeeding sections the determination of *rent* in its various senses will be discussed.

**In common usage.** As used in everyday speech, *rent* means a payment for the services of a material asset for a specific period of time. As such, rent is comparable to the wages of labor, and, as suggested by Frank Knight, both wages and rent might be classed under the heading *hire value*. The term *rental value* might also be used for what is commonly called rent to avoid confusion with the technical economic meaning of rent. Real estate, or land and buildings, is the type of asset most frequently rented, but a wide variety of other consumer and producer durable goods are rented as well.

Renting or leasing as an alternative to ownership may take place for a variety of reasons, one of which is infrequency or short duration of use relative to costs of purchase and sale. Houses or apartments are typically rented by smaller households, probably because small dwellings are relatively more costly than larger ones when provided in the form of single-family dwellings, and by younger families, who have little accumulated nonhuman wealth (i.e., wealth other than their ability to earn income with their own labor) and for whom the interest cost of capital invested in ownership is high. Business firms may choose leasing in preference to ownership for quite similar reasons. In addition, renting of any asset may be preferred by households or business firms that have a greater than average aversion to the risk of the change in value of assets that ownership entails.

The actual rental payment made by the user of an asset includes several components. First, gross rent, or rental value, includes a payment to cover depreciation, which is the decline in the value of the asset during its period of use. Second, where the owner rather than the user of the asset is liable for payment of property taxes, as is typically the case in the United States, the rental payment will include an allowance to cover these taxes. The rental payment, like an interest payment, may also include a component to cover the cost of making and servicing the lease agreement. And finally, the rent of any asset includes a payment to cover interest

costs on the value of the asset during its period of use.

There are a variety of special types of rental payments. The term "ground rent" refers to a payment for the use of land on a long-term lease, frequently 99 years. Such payments provide a relatively sure and very stable income stream, which some investors find attractive. "Space rent" in the consumer expenditure tables of the U.S. national income accounts refers to the rental value of a structure and the land on which it is situated, apart from any payment for utilities and furnishings supplied by the landlord. In the U.S. Census Bureau reports on housing, "contract rent" means the payment agreed on by tenant and landlord and includes any payment for utilities and furnishings supplied, while "gross rent" refers to contract rent plus the estimated value of all utilities not furnished the tenant by the landlord. Finally, the "rental income of persons" as a component of the U.S. national income accounts refers mainly to the income actually received directly by households from rented nonfarm property and the imputed net return from owner-occupied nonfarm housing. It also includes the net returns received by persons from farm real estate, but this component is small relative to the other two. It should be noted that the rental income of persons shown in the U.S. national income accounts includes only a small fraction of the rental value of land or of material assets generally. Most rental income is actually paid out in the form of corporate income or income to unincorporated businesses.

**In classical economics.** Economists realized quite early that much of what is commonly called rent is really nothing but the return to the various forms of capital investment. Thus, the classical economists reserved the term "rent" for a type of payment they believed to be qualitatively distinct from wages and interest. This was that part of the landlord's return for the use of "the original and indestructible powers of the soil," as Ricardo put it. Rent of land in this sense might arise because of the limitation on its quantity, as stressed by Malthus, and this type of rent was sometimes called "scarcity rent." Land rent might also result from differences in fertility and location. Rent arising from this source was frequently called "differential rent." It is easy to make too much of the distinction between scarcity and differential rent, however, since the most fertile or favorably located land would earn a differential return over other land only if the former were scarce. [See the *biographies* of MALTHUS; RICARDO.]

Ricardo especially stressed that the most fertile

and favorably situated land would be cultivated first. With the increase in population and wealth, according to Ricardo, land of inferior quality is taken into cultivation. The exchange value of raw produce would rise because more labor (and capital used with labor in fixed proportions, presumably) would be required to produce on the less fertile land. The first land would then yield a return equal to the difference between the produce obtained by the employment of equal quantities of capital and labor on each quality of land. Rent, Ricardo argued, does not enter into the cost of production. The latter is determined by the quantities of other factors employed at the margin of cultivation on land that yields no rent. "Corn [i.e., food] is not high because rent is paid, but a rent is paid because corn is high," in Ricardo's words.

Even in the more limited sense in which the term was used by the classical economists, it is difficult to ascribe the returns to land to some "original and indestructible" properties of nature. In a very real sense, land as a productive factor was created as capital by pioneers who gave up other income in traveling to and preparing the land for cultivation. To these pioneers, the return to their land after an allowance for the obvious costs of buildings and other visible improvements was merely a return to their earlier sacrifices. To later owners of the land, its return was merely a return to their fluid capital, which might alternatively have been used to acquire other material assets. Land today is reclaimed through irrigation and drainage, and its fertility is obviously capable of exhaustion. In addition, the supply of favorably located land is continually being increased by improvements in transportation. Finally, when land has more than one use, the maximum income it can earn in alternative uses is a part of the cost of production for the commodity it helps to produce. Thus, oranges may be expensive because of high returns to land used to grow oranges if the high returns to land upon which oranges are grown result from its high value for alternative residential and other urban uses. [See COST.]

Not only is land reproducible and destructible in much the same way as other material assets but other assets may possess properties similar to those the classical economists ascribed to land. Any productive factor, including labor, is limited in absolute amount and thus earns a return that results from its scarcity. Quality differentials exist for most classes of productive factors no matter how narrowly defined; differential incomes are earned by members of a particular class of productive factor as a result of their differing productivities.

And many productive factors earn incomes that exceed the minimum amount necessary to insure their employment in the specific use to which they are put.

In modern economics. For reasons such as these, economists today rarely think of rent as a qualitatively distinct type of payment accruing to a specific type of productive factor. Rather, "rent," along with the terms "cost" and "profit," refers to types of payment that may be included in the income of the owner of any kind of productive factor. These types of payment are distinguished in terms of (1) the minimum payment necessary to induce a factor into a specific use, (2) the payment a factor owner expects to receive when the factor enters or remains in a specific use, and (3) the actual payment received. Rent is the excess of a factor's expected return or income over the minimum necessary to bring forth the particular service to its specific use. Cost is the minimum necessary payment, while profit is the excess of the actual payment received over the expected payment when the resource was committed to the specific use. The term "entrepreneurial rent" is frequently used to describe the expected return to a firm over and above the minimum necessary to induce the firm to enter or remain in a specific industry. It corresponds to what is sometimes loosely thought of as profit.

That part of a factor payment termed rent by the present-day economist is, like the classical economist's rent, price-determined rather than price-determining. It is important to realize, however, that the distinction between cost and rent is a flexible one and depends critically upon the range of alternatives considered and upon the time period allowed for adjustment to changed conditions. For the economy as a whole, the return to many human and material productive services is wholly rent, since no other uses are available for and hence no opportunities are forgone by some employment. To any specific user of a particular productive service, in contrast, the payment he makes is wholly a cost if the productive service could earn as much from another firm in the same industry. In general, the broader the range of alternatives open to a productive service, the larger is the portion of its income that is a cost and the smaller its rent.

The distinction between cost and rent also depends upon the time period for adjustment one considers. For very short time periods most human and material assets are in effect fixed in their current uses. Thus, any return to their owners over and above the minimum return necessary to insure

that they be employed at all is rent. The longer the period of adjustment one considers, the greater the number of alternative employments that become available and the smaller the rents. In the longest of all long runs many factors of production have a great number of alternative employments, and in consequence their incomes are mostly cost. The term "quasi rent," introduced by Alfred Marshall, is used for a payment, especially to the specific material embodiment of nonhuman capital, which is rent in the short run but a cost in the long run, that is, when the capital is no longer fixed in a specific material form.

Finally, it should be stressed again that in the modern sense of the term, rent may be a part of the income of any productive factor. It has already been pointed out that the incomes accruing to material assets are largely rent so long as the specific material form of capital is fixed. In addition, actual wage and salary payments consist in part of rents in differing degree, depending upon circumstances already noted. The salaries of college professors, for example, may be largely a cost to any particular institution that employs them. From the viewpoint of all institutions of higher learning, however, the excess of the incomes of professors when adjusted for nonmonetary advantages over the incomes they might earn in government or industry is rent. Considering all potential employers of college professors, most of a professor's income is rent once he has made his occupational commitment. The same expected income may be largely a cost, however, before an individual chooses to enter college teaching in preference to some other occupation.

### Determination of rent

In this section the principles of the determination of rent are discussed. Rent as rental, or hire, value is considered first; this is followed by a discussion of the determinants of rent as an excess of expected return over cost. Because rent is so often thought of as the return to land, special attention will be given to the level of land rentals generally. This section will conclude with a discussion of the share of returns to land in the national income. The discussion of the returns to land is continued in the third section, where differences in land rentals attributable to differences in location are discussed.

**As rental value.** The determination of the rental, or hire, value of an asset is but a specific instance of the determination of the prices of productive services generally. In any specific use or industry

the rental value of a particular material asset is equal to the price of the final product multiplied by the marginal physical product of the services of the asset in the specific use, provided that competition prevails in both the product and the factor markets. The marginal physical productivity of the asset's services, in turn, varies directly with its scarcity relative to other productive factors. It is analytically useful, as in any problem of price determination, to separate the forces affecting rental value into (1) demand for the services of an asset in a particular industry as derived from the demand for the final product produced by the industry, (2) the supply of other productive factors to the industry, and (3) conditions of technology. For the economy as a whole, the demand for an asset's services is simply the summation of all the individual industry demand curves, provided that conditions of supply and technology for the economy as a whole are used in deriving the industry factor demand curves to be summed.

An increase in the demand for final product tends to raise both the rental per unit of an asset and the aggregate of rental payments to the asset in question. In general, an increase in the supply of other productive factors will tend to reduce the demand for the factor in question as these other factors are substituted for it in production. (It is possible, of course, for an increase in the supply of complementary factors to increase the demand for the asset in question, but on balance all other factors taken together are substitutes.) On the other hand, the increase in supply of other factors leads to an expansion of the industry's output and, hence, an increase in the demand for the asset in question. The strength of the increase in demand operating through the expansion of output is greater, the greater the elasticity of demand for the industry's product. The substitution effect varies directly with what is technically known as the *elasticity of substitution in production* between the asset in question and all other factors, that is, the relative change in the ratio of the input of the asset in question to all other factor inputs, divided by the relative change in the inverse ratio of their marginal physical productivities when output is held constant. Its value varies from zero, in the case where the asset in question is used in fixed proportions with all other factors, to plus infinity, where the asset in question and all other factors are perfect substitutes. The net effect of an increase in the supply of all other factors will be to increase or decrease demand for, and hence rental value of, the asset in question, depending upon

whether the elasticity of industry demand is numerically larger or smaller than the elasticity of substitution in production.

A technological change that increases or reduces the marginal productivity of the asset in question but leaves output unchanged will increase or reduce its demand and rental value. A neutral technological change, or one that increases the marginal productivity of the asset in question and all others in equal relative amounts, will increase or reduce the demand for, and rental value of, an asset, depending upon whether the elasticity of demand for the industry's product is numerically greater than or less than one.

In applying the above propositions to land rents it is important to distinguish between agricultural and urban uses of land. It would appear that the demand for agricultural output is highly inelastic with respect to its relative price and that the elasticity of substitution is about unity. On the other hand, the price elasticity of demand for housing, by far the most important use of urban land, is probably unity or even larger numerically, and the demand elasticities for many other urban products may well exceed unity. Since aggregate land values would appear to be large relative to the total value of structures near the centers of cities, where rentals per unit of land are high, the elasticity of substitution of land for other factors in producing most urban products is probably less than unity. Thus, it would appear that an increase in the supply of nonland factors would reduce the demand for, and rental value of, agricultural land and increase them for urban land. Also, a neutral technological improvement would reduce the rental value of agricultural land but leave unchanged or increase urban land rentals.

The supply schedule of a particular productive service to a specific use or industry is merely the aggregate supply schedule of the factor less the demand schedule for the factor in all other uses. At the edge of cities, for example, the total quantity of all land is fixed, and the supply of land for residential and other urban uses is this fixed quantity less the demand for agricultural land. The demand for the output of agricultural firms in the vicinity of cities is highly elastic, since this output is but a small part of the total national or world output. One would therefore expect the agricultural demand for, and the urban supply of, land at the edges of cities to be highly elastic.

Little can be said generally about the aggregate supply schedule of a productive factor facing the economy as a whole. However, the shape of the

aggregate supply schedule depends critically upon the length of time allowed for adjustment, certainly so for nonhuman agents of production. Probably because it is quite costly to add rapidly to the stocks of most material assets, their supplies tend to be highly inelastic over short periods of time. In the long run, the relative supply of most material assets—for example, houses as opposed to office buildings—may well be highly elastic. Since it would appear that the rate of saving is relatively insensitive to the rate of interest, the aggregate supply of all material assets or of capital to the economy is likewise probably relatively insensitive to their rental value.

An increase in the supply of an asset will lower its rental value per unit, but the aggregate rental value of all assets of a given type will increase or decrease depending upon whether the price elasticity of the factor demand schedule is numerically larger or smaller than unity. Provided that the supply of other factors to a specific industry is highly elastic, the demand elasticity for the services of a particular asset is a weighted average of the (negative of the) elasticity of substitution in production and the demand elasticity for the product; the weights are respectively the fraction of the industry's receipts paid out to all other factors and to owners of the asset in question. Thus, the demand for the services of land is likely to be inelastic—in agriculture because of the inelastic demand for the final product and in housing and other urban uses because of the less than unit elasticity of substitution in production. In either case, an increase in the supply of land, as might be brought about, in effect, by an improvement in transportation, would reduce the aggregate rental value of land.

As excess of expected return over cost. All of the forces that affect rent in the sense of rental, or hire, value also affect rent as the excess of expected return over cost. For any particular unit of the productive service actually devoted to the specific use, rent is merely the difference between the expected market price and the ordinate of the factor supply schedule at that quantity at which the particular unit enters into the specific use. In Figure 1, for example, units of the productive service that would enter the specific use at a price per unit of  $OD'$  receive a rent equal to  $D'E$  when the market price is  $OE$ , as under the conditions illustrated. The aggregate rent paid out to all units of the factor employed in the specific use is the integral of expected price minus the ordinate of the supply schedule taken over all units of the service employed in

Figure 1

the specific use, the triangle *CEF* in Figure 1. Clearly, any event that causes the demand for the factor to increase, increases the rent received by each unit of the productive service and the aggregate rent received by all taken together. An increase in the supply schedule reduces the rent received by any given unit of the productive service. However, an increase in supply may either increase or decrease aggregate rent paid. If, for example, the supply schedule is perfectly inelastic, the whole of the expected payment to the factor is rent, and this total payment increases or decreases as demand is elastic or inelastic.

Rent as an excess of expected return over cost depends critically upon the slope of the supply schedule. Given the point of intersection of the demand and supply schedule, the steeper the supply schedule, the greater the rent received by any unit of the service and the aggregate rent received by all. In the case of labor, or the services of human beings, the slope of the supply schedule for a particular occupation varies directly with the extent of differences among individuals in their abilities to perform specific functions and, perhaps more importantly, with differences in their evaluations of the nonmonetary disadvantages or attractiveness of the occupation relative to others. Nonmonetary considerations are generally of little importance for most nonhuman assets.

**Share in national income.** The final topic considered in this section is the share of aggregate land rentals in the national income. This share, or the share of any factor, depends critically upon the elasticity of substitution between it and all other factors in production. An increase in the

supply of other factors relative to land increases the aggregate of all land rentals relative to the national income, depending upon whether the elasticity of substitution is less than or greater than unity. A neutral technological change likewise increases land's share if the elasticity of substitution is less than unity, provided that, as is probably the case, the elasticity of supply of land to the economy as a whole is less than that of all other factors. Of course, a technological change that increases land's marginal productivity and reduces that of other factors, leaving output unchanged, will increase land's share.

It has been asserted earlier that in agricultural uses the elasticity of substitution of land for other factors is about unity, while for urban uses of land this elasticity would appear to be less than unity. For the economy as a whole, the elasticity of substitution also depends upon the substitutability of agricultural for urban products in consumption. The very low relative price elasticity of demand for farm products suggests that substitution possibilities in consumption are small. This last consideration, coupled with the fact that urban output is large relative to farm output, suggests that for the economy as a whole the elasticity of substitution of land for other factors is probably less than unity. While data are very scanty, it is probably true that the returns to land are a smaller fraction of the national income in the more highly developed economies, including the United States, and have grown less rapidly over time than has national income. Such tendencies might result from the relative increase in land supply brought about by improvements in transportation with economic development or by the fact that the demand for land-intensive commodities, such as farm products, grows relatively less rapidly than the national income.

**Location rents.** This section continues the examination of the rental value of land by considering differential rentals attributable to differences in location. Such differentials are frequently referred to as "location rents" and are the major source of differences in the rental value of different parcels of urban land. While of interest for their own sake, differential land rentals are especially important because of their relation to the spatial organization of economic activity.

The first economist to undertake an investigation of the spatial aspects of economic activity in any detail was von Thünen. He postulated a single city located in a boundless plain of land of homogeneous quality in which transportation costs varied with distance from the city but were otherwise invariant. (This is what has since come to be

known as a "transportation surface.") He then showed that different types of farming would be arranged in annular (that is, ringlike) zones around the city. Commodities for which transport costs were relatively high—milk, for example, because of its perishability—or for which land is relatively unimportant would tend to be produced in the inner annuli, and commodities for which transport costs were low and land important would tend to be produced in the outer ones. Land rentals declined from annulus to annulus, and within a given annular zone the difference in land rental was equal to the difference in costs of production plus transportation to the market in the city.

In most developed countries today agricultural produce tends to be traded in national or world markets. Transportation costs to a particular market, except for a few commodities such as dairy products, have relatively little effect on the location of agricultural production. Thünen's analysis, however, is highly relevant for the analysis of land use in cities or urbanized areas and, in fact, is the basis for most modern economic theories of city structure. It also bears a striking similarity to the concentric-zone theory of city structure, developed by the sociologist Ernest W. Burgess about a century later. In theories of city structure, the central business district (CBD) plays the role of Thünen's isolated city. Located near the hub of the city's internal transport system, the CBD is generally the area of maximum accessibility to the local market for commodities and services of many kinds and to the local labor market. In addition, since rail terminals are typically located adjacent to the CBD, it is close to outside markets and sources of supply. (With the advent of highway and air transport, however, the comparative advantage of the CBD on this score has declined.) Since the CBD is generally the largest single employment and shopping center in the city, accessibility to the CBD is especially important for residential users of land. [See the *biographies* of BURGESS; THÜNEN.]

In the analysis of the relation of land rentals to the location of economic activity in cities, four distinct kinds of considerations are relevant. First, provided that competition prevails, any given user of land takes the prevailing level of rentals in any location as given. The use of land relative to other productive factors is governed by the principle that to minimize the cost of producing any given output, the firm adjusts its inputs in such a way that the marginal physical product per dollar spent is the same for all inputs. Thus, where land rentals are high relative to the prices of other productive services the marginal physical product of land is

relatively high. This means, for example, that high-rise apartment buildings tend to be built where residential land rentals are highest, as do loft-type or multistoried factory buildings in commercial areas of relatively high land rentals. Conversely, single-family detached houses and single-story factory buildings tend to predominate in areas of relatively low land values.

Secondly, for firms of any given industry to be in locational equilibrium, it is necessary for land rentals to vary directly with the price received for their product and inversely with the price paid for productive factors other than land, both being measured at the point of production. If, for example, firms located closer to the CBD received higher prices for their products but all firms paid the same rentals per unit of land, firms closer to the CBD would earn larger incomes. It would then be in the interest of firms located further from the CBD to offer more for the closer sites than firms located there were currently paying. In the process, the rental of sites closer to the CBD would be bid up, while that of more distant sites would be bid down. In general, the conditions of firm equilibrium require that the relative variation in the rentals of land used by firms in a given industry be greater, the more product or nonland input prices vary relatively with respect to location and the smaller the share of land in the receipts of the industry. The variation of final product and input prices with location results primarily from transport costs. Transport costs on final products or raw materials, in turn, tend to be greatest for small shipments and shippers, for bulky and difficult-to-handle goods, and for goods of high value in proportion to weight. The costs of transporting people, both as buyers of final products and sellers of labor, are also important determinants of rental gradients.

The third consideration relevant in the determination of differential land rentals might be called equilibrium in the market for land. Equilibrium requires that each parcel of land be devoted to that use which yields the highest rental. For if this were not the case, landowners could increase their incomes by leasing their land to firms in alternate industries. Both the amount of rental offered for land at any location and the rate of change of rental with change in location, or rental gradient, are important in allocating land among industries. If in the vicinity of any center of activity, or local peak in land rentals, firms of two different industries are to locate, firms of the industry with the steeper rental gradient will locate closer to the center. This follows from the fact that if the func-

tion showing the rental one industry offers for land is anywhere above that for the other industry, it will be so at the center. Therefore, as one proceeds out from any local peak in land values, the relative decline in land rentals will diminish in passing from the area of location of one industry to another.

It should be noted that taken together, and in the absence of external economies in land use, the conditions of locational and land-market equilibrium imply that the rental value of land is maximized. Maximization of rental value is requisite to efficient resource use. In actual practice, of course, external economies in urban land use may be of great substantive importance, and in the absence of conscious social control the bidding for land by private individuals and business firms may fail to maximize the rental value of land. This failure provides the economic rationale for planning, zoning, and other forms of governmental land-use control. Now, it is frequently stated that the aim of governmental land-use control is the minimization of land rentals. The reasons for this view are interesting but not relevant here. Its absurdity is readily seen by considering that an absolute minimum of land rentals could be achieved by forbidding land to be used for any purpose whatsoever.

Finally, for any pattern of locational differences in land rentals to be an equilibrium pattern, it is necessary that there be no unsatisfied buyers or sellers of any commodity at any point in space. For if there were, the prices of some commodities would rise or fall, and the maximum rentals offered for certain parcels of land would likewise change. As a result, it would be profitable for some landowners to change the use to which the land they own is put.

Having outlined in very general terms the principles underlying the determinants of differentials in land rentals with location, let us consider some specific forces governing actual rental differentials. It was noted earlier that the CBD is the area of maximum accessibility or minimum transport costs for the local product and labor market and that it is convenient to the rail lines serving as links to outside markets and material-supply sources. The relatively high cost of local movement because of traffic congestion in the center, especially during rush hours, may mean that prices received for products rapidly fall off or wages paid increase rapidly with movement away from the center. Where actual transport of goods is involved, the products of CBD firms are generally of high value in relation to weight and often involve small shipments or shippers, so that transport costs are relatively high. Finally, for the commercial, trade, and

service firms that locate in the CBD it would seem that land is a relatively unimportant factor of production.

Agriculture, on the other hand, is probably the most land intensive of all economic activities, and shipments of agricultural products are frequently large and involve products of relatively low value in relation to weight, so that transport costs are relatively low. Thus, commercial and retail firms, residences, and agricultural firms are located in roughly annular zones surrounding the CBD, and land rentals decline at progressively lower rates in each of these zones.

There are, of course, many exceptions to the broadly annular zonal pattern of location and corresponding relative declines in land rentals surrounding the CBD. The two most important are the concentration of manufacturing in the vicinity of waterways, rail lines, and truck routes and the more or less regular hierarchical pattern of retail and service business. It is well known that the structure of transport costs is such that manufacturers and other processors tend to find locations at point material sources or markets less costly than intermediate ones. While sources of raw materials are rarely found inside city limits, rail lines, freight and truck terminals, and waterways are essentially point or linear material sources and markets for final products for shipment outside the city. The so-called light manufacturers, firms receiving or sending shipments in less than carload lots, find location close to freight terminals desirable. The same is true for wholesalers whose outbound shipments are frequently less than carload lots. Since land is probably a more important productive factor for light manufacturers and wholesalers than for commercial, retail, and service firms in the CBD proper, the former group tends to locate around the outer edges of the CBD. In this area of location, land rentals probably decline relatively less rapidly than within the CBD proper, although more rapidly than in the surrounding residential zone. Heavy manufacturers or firms receiving or making shipments in carload lots would find locations anywhere along rail lines or truck routes equally attractive. As a result there is no reason relating to transport costs on commodities to expect land rentals in immediate proximity to such routes to vary with location along them.

The tendency for retail and service business to concentrate in a hierarchy of centers of various sizes at more or less regularly spaced intervals or along major streets within a city is explained by central place theory [see SPATIAL ECONOMICS]. In addition, because certain facilities, such as parking lots, are shared, some costs are lower in shopping

centers than elsewhere. The demand for any particular firm's product is probably greater within a center because of the tendency for customers to make a variety of purchases during any given trip and to comparison shop, and the vicinities of certain points, such as intersections of major streets and rapid transit stops, are points of local minimum transport costs for many kinds of firms. The reasons given for the relative steepness of rental gradient within the CBD apply, but with diminished force, in these non-CBD retail and service centers. Hence, the rental value of land is likely to decline relatively rapidly in the vicinity of these outlying centers. It would appear that the peaks of land rentals are relatively higher in the centers belonging to higher levels of the hierarchy, the highest of which is the CBD, but there is no reason to expect the peaks of rental value in any given level of the hierarchy to vary systematically with location in the city.

Within the residential zone housing prices decline with distance from the CBD. If this were not the case, households located closer to the CBD, and bearing lower transport costs to and from it, would be better off than households in more distant locations. It would then be in the interest of the more distant households to offer more for housing closer to the CBD than its current inhabitants paid, and a decline in housing prices with distance from the CBD would result. Now, it can be shown that a necessary condition for household equilibrium is that the relative rate of decline in housing prices per mile, say, be numerically equal to a household's additional expenditures on transportation per mile divided by its expenditure on housing. Households with relatively high transport costs, such as those with more than one worker employed in the CBD, have an incentive to locate close to the CBD. Those who spend greater amounts on housing likewise have an incentive to locate at greater distances. Thus, the relative rate of decline of housing prices is smaller in the outer parts of the city, and for this reason land rentals would decline at relatively slower rates at greater distances from the center. This last tendency is at least partly offset, however, by the fact that because of the less than unit elasticity of substitution of land for other factors, the relative importance of land in producing housing is smaller in the outer parts of cities. Because transport costs tend to be smaller for households located in the vicinity of rapid transit routes and express highways, land rentals decline relatively less rapidly with distance from the CBD in the neighborhood of these facilities.

Housing prices in cities, and thus land rentals, may vary for many other reasons. Since accessi-

bility to local shopping and employment centers, rapid transit stops, and educational, cultural, or recreational centers has value because of the saving in transport costs, one might expect local variations in residential land rentals in the vicinity of the centers. In addition, the prices people are willing to pay for residences are undoubtedly influenced greatly by the character of the surrounding area. It would appear, for example, that housing prices, and thus residential land rentals, are lower in the immediate vicinity of local manufacturing centers and higher in higher-income neighborhoods and in the immediate vicinity of attractive natural surroundings.

## REPRESENTATION

- I. THEORY
- II. REPRESENTATIONAL SYSTEMS
- III. REPRESENTATIONAL BEHAVIOR

Alfred de Grazia  
Giovanni Sartori  
Kenneth Janda

#### THEORY

Representation may be defined most usefully as a relation between two persons, the representative and the represented or constituent, with the representative holding the authority to perform various actions that incorporate the agreement of the represented. The relation is by no means simple, since practically every type of human communication and perception can be shown to be intrinsic to representation. The relation is sociopsychological. Essentially subjective, it may, however, be affected by numerous objective conditions and events.

Representation is a concept of social interest largely in the contexts of power relations among leaders (representatives) and followers (constituents)—whether in government, church, school, business, or the family. It may well be noted in terms of a scale ranging from nonrelation (or “bad” relation) to perfect or full relation. Thus an accord of  $x$  degree has to be achieved before representation may be said to exist; below that point, A is said not to be represented by M.

### The study of representation

The simplest index of representation is a positive answer that a person may give to the query: “Do you feel represented by M?”

What this degree of accord is to be is not standardized, if only because the very parameters of the relation are unexplored. When H. F. Gosnell and this writer attempted such an exploration in 1940 (see Gosnell 1948), it was plain that the classical utterances on political representation were commonly polemical, unsystematic, and superficial (cf. Burke 1774; Mill 1861; the materials presented in Loewenstein 1922; Clarke 1936; Smith 1940). As soon as the thicket of representative relations was entered, progress became slow. Obviously representation must consist of unconscious as well as conscious relations, expressive as well as sanctioned actions, unknown as well as known actions. Otherwise one falls into the trap of regarding as determinative of the representative relation solely conscious, known legislative behavior—parameters that are more often missing than present in the setting about which the scholar wishes to say “A is represented by M.” This rationalistic fallacy has prevented generations of scholars of democracy from coming to grips with problems of representation (de Grazia 1951).

Today, by contrast, the study goes forward. John Wahlke, Heinz Eulau, William Buchanan, and L. C. Ferguson (1962) managed to perform the difficult task of fitting standardized inquiries of several sets of U.S. state legislators into the real-life environment of representation and attaching to the representatives’ cognitive and perceptive structures and functions a set of postures toward representation: the *expert* role defines the ability and reputation of a member with respect to the work of the assembly; the *purposive* role includes the ritualist and the tribune who defends the people; in the *representative* role some legislators take up a trustee posture toward their constituents, others take a delegate posture, and some “politicos” are disposed to both in various ways; finally, the *areal* role denotes the tendency toward identifying with

the elective district, on the one hand, and the whole state, on the other. At about the same time, Warren E. Miller and Donald E. Stokes (1963) undertook to question samples of the electorate of various districts concerning their congressmen.

As they have exposed the facts of representation, recent studies have also disclosed the materials upon which the long-argued ethics of representation must rest. The question “Whom should a representative represent?” can be answered precisely, granted always that one knows what it is he wishes the representative system to produce by way of action or expression.

**Clarifying the concept.** Despite the improvement in research, the connection of representative and constituent in any setting or in society as a whole must continue to be referred to imprecisely in absolute terms (“is”—or “is not”—“represented”), or in imprecise comparative terms (“more representative than”). What would be required to make the terminology more precise?

First of all, a clear, scientific approach to the myth-shrouded concept is required. Considering the wealth of empirical investigation in human relations, it is odd and regrettable that so little work has borne directly upon the foremost structural problem of democracy.

The state of knowledge of representation would also be improved if translation of concepts and findings of other scientific fields were made. Since representation is a psychological condition, there are obviously numerous relevant concepts, such as perception (awareness), cognition (information), communication, stereotypes, and authority (charisma), that are to be regularly taken into account.

In addition, there are many group-behavior concepts that pertain to representation. If representation is a relation between A and M, it is also a relation between B, C, D, . . . , on the one hand, and M, on the other, the group boundary of the members being the electoral constituency, which in turn can take numerous territorial or functional forms and can exclude a few or most of the population.

**Determining representativeness.** What determines the representation of a group’s members and the selection of their formal leaders? Numerous variables do. They may be either constructed or naturally occurring variables, such as the social composition of the group and its aggregate attitudes toward personality types and public issues. In all attempts to influence or study these variables, it must be remembered that every force brought to bear upon A will perhaps affect B, C . . . , differently. This obvious fact has highly complicated

meanings for electoral study. The effects of propaganda, for example, although difficult to measure, are highly germane to the study of representation. A major source of change in representation may be the propagandistic operations of parties contending for the right to be representatives.

If propaganda is regarded as stimulus, intended to cause responses favorable to the propagandists on the part of the propagandized (admittedly the represented are continuously being propagandized), the chances of success of the stimulus rest upon its penetration of the more basic norms of the population. If, for example, the expectations and demands of a group are heightened by the winds of an ideology new to its members, or by re-education according to nontraditional principles, increased pressures will be exerted upon those who offer themselves as representatives. The latter will be obliged to respond by messages of a confining or, more likely, exhorting nature.

In sum, the study of the representation of a group results from the special algebra of aggregations of individuals. Two theories of representation, one for individuals and the other for groups, are not necessary. Admittedly, if it is difficult to assess the condition of representation of a single person, extending a set of such single calculi to cover an aggregate of thousands would give findings of dubious validity. Still, counterbalancing and averaging errors of individual estimates permit the result that a statement made about the representation of a group is likely to be no less precise and may even be more valid than one made about an individual.

### Representative government

Thus far, we have spoken of individual and group psychology in representation as being affected by subjective and symbolic determinants. There also exist as determinants a great number of institutional devices to produce (or restrict) representation. Election systems, nomination systems, campaigning systems, etc. are the devices. These devices, which may sometimes be called institutions but often are of a relatively minute nature (such as a term of office), are to be construed as recurring sets of similar actions relevant to the relation of representation—habitual, routine, predictable, and enforced by specialized personnel. There is no need, therefore, to separate the study of representative government from the study of representation.

A group of institutional devices intended to produce a high level of representation in a population may be called representative government. Historically, many governments have been representative

without being representative governments, since the conditions for representation may be "ideal" without the employment of institutional devices. One can readily point to direct democracies, which have existed in many times and places—the ancient Greek cities, areas of sub-Saharan Africa, the Italian cities of ancient, medieval, and early modern times, the Teutonic tribes, and the New England town meetings. They need not be defended as models of representation in order to accept the premise that their peoples received on the average as much representation as, or more than, other peoples have received under representative governments. Actually, were it not for the fact that a largely mythical distinction is made between "true" representative government and "direct democracy," we should lump the two together, not only because of the similar effects produced, but also because of principles and machinery of choice (elections) and control employed in both cases: the Athenian lottery brought forth officers who were supposed to represent the citizens in the same sense as the presidents chosen by modern election.

More bothersome to theory is the absence of the devices of representative government in certain groups where a high degree of over-all representation exists, such as Nazi Germany—between 1935 and 1942—Augustan Rome, and Napoleonic France, and, worse, the apparent absence of representation in certain representative governments, such as the United States under John Adams and the Soviet Union under Stalin.

**Institutional devices.** What is the nature of this cluster of devices—nomination, apportionment, election, ballots, campaigns, etc.—that is called representative government? Theoretically they have to be regarded as procedural constructions intended to form representation in a desired way. Thus, an apportionment that follows local cultural boundaries is expected to produce representatives colored by local ideas, and one that cuts across boundaries in a nearly random way is supposed to suppress established localism. A single-member district system in which a majority or plurality vote determines the winning candidate is expected to accentuate the majority sentiment of each district; whereas a multimember district in which any considerable minority is bound to elect at least one candidate, is a device intended to enrich legislative discussion by presenting opposing views from the same constituency.

Thousands of such variant election systems might exist, although, because of imitative forces, there are in fact mere hundreds. Only the fool or ideologue insists that one system is the only system

of representative government. Indeed, as we have indicated, it is impossible to show that representative government produces a strikingly larger representation of the population than other forms of government. However, as representative government becomes more understood, and more controllable, its devices may be arranged to produce with fair accuracy the fuller representation of whomever the system is set up to represent.

It is important to stress that the devices of representative government are not all things to all people. They help certain people to get more representation, and this is performed almost always at the expense of someone else's representation. Each successive change in history (and in the great many short-term cycles of history that occur from year to year in contemporary society) has meant a redefinition of who is "worth" representing in a people. Attitude, procedure, and device always go together, one often canceling out the effect of another. For instance, the kind of representation available to citizens of American states from their state legislatures was changed by court order in *Baker v. Carr* (1962) and *Reynolds v. Sims* (1964) to provide districts of equal population, but simultaneously the total representativeness of the legislatures was, perhaps temporarily, reduced when many unfamiliar candidates presented themselves to the people. In a more permanent way, perhaps, the political power of rural and small city areas was cut down. (For other effects of these cases on the condition of representation, see de Grazia 1963.) Disturbing a set of relations that is premised on awareness and acquaintanceship can easily reduce representation in the very setting where new devices are intended to promote it.

Thus the devices of Italian and German representation were modified after World War I to permit more accurate manifestations of public opinion in the legislatures. Proportional representation was employed, for example. Some of the effects were as foreseen—representativeness was increased—but the largest effect of the innovations was to promote a contrary form of representation, based upon the *Duce* and *Führer* principles, i.e., direct, controlled representation of the people, emphasizing uncontrolled, unrepresentative activity on behalf of the mass (Hermens 1941). In quite another way, far from "strengthening the state legislatures," as the Supreme Court maintained in associated opinions, the aforementioned 1962 and 1964 American cases could perhaps hasten the decline of federalism and, within the states, diminish the role of the legislature in relation to that of the governor.

These instances permit a proposition about changes in representation. Representation is broader

than the devices that regulate it. Classical speculation and debate over representation have almost always looked on representation as a linear scale relation: a device would either increase or diminish representation. This is true, or can be made to be true, if the question that operationally defines the relation is simplified; for example, one may ask, "Do you feel more or less represented today than five years ago?" Alternatively, representation can be confined, usually unconsciously, to a certain kind of issue: "Has your representative followed your wishes with respect to voting on the budget?" A man with an atomistic view of society may consider this an adequate test of whether representation exists. However, many changes in representation could occur that would not be tapped by such questions and therefore would not be measured at all and might lead to a false general interpretation.

One must conclude that the burden of plotting and mapping the effects of disturbances and changes in most devices of representation is too heavy for contemporary political science to bear and far too heavy for the much more limited rationality of practical politics. Although each institutional device can be perceived to carry certain effects, such effects are not well known, either scientifically or in applied politics. If its individual effects can be predicted, its indirect effects when taken as part of a system of devices cannot; the coming of other changes cannot be foreseen either, and these may be of a character so gross as to overwhelm the effects of the initial change.

### The role of representation

Representation is multifaceted. It is a broad relation. To define it otherwise invites continual frustration. To be useful in the traditional scope of its usage, it has to be defined as broadly as the range of expectations that people possess in regard to government, and hence in regard to public officials and leaders (*pari passu*, representation within all social organizations should be so defined).

Since many traits, events, and institutional devices affect the state of representation, the represented is approachable along numerous paths. It may, therefore, be sensed as only a small loss to him to be deprived of a vaguely familiar, "trivially" occupied district representative, when at the same time he is receiving a new charge of emotional satisfaction from a physically remote but psychologically near national figure. It is as useless to berate him for shortsightedness, romanticism, and foolishness as to berate any other mystic who shuns the practical. Indeed, this mysticism is more practical, for it costs nothing in self-discipline.

One conclusion about this particular phenomenon may be that only a self-disciplined ruling class, inured to the presences of commanding personalities and individuals of high status, can operate a republic over a long period of time; the mass of the population must succumb sooner or later to the seductive choice of the great over the petty, majesty over meanness, feeling over calculation. This elite need not be one of birth—it can emerge from the great population—but it must have two traits if it is to function in the bosom of modern mass democracy: (a) it must have a means of maintaining solidarity on the principles of multifaceted and rationalistic representation despite the surge of the mass of people toward single-executive leadership, and (b) it must have the skills to govern the masses.

The crisis of representation in the twentieth century has been precisely the inability of the old ruling class that created the rich fabric of representation to maintain its solidarity and guide the whole population. Thus in Russia, Italy, Germany, Spain, Japan, Argentina, and France, to name only the important catastrophic cases, the exaltation of executive representation overcame the intricate and ramified system that had developed.

Today, after the historical experience provided by these cases, public opinion seems in a less dangerous state. Yet the United States and the Soviet Union both face permanent crisis over the mode of representation to be provided their populations. The Soviet Union depends on an ideological elite party to ward off single-executive dictatorship. The United States depends on a complicated legalistic set of representative devices and localized parties and elites. Neither is safe; neither is advancing toward the vision of representation developed according to humanistic principles whereby, as John Dewey described it, a citizen lives a life of enriching communion with his fellow men in an associational society (1927; cf. Follett 1918).

The vision of a pluralistic or "mobilistic" system that represents plural types of men and plurally complicated persons stands in sharp contradiction to the idea of monolithic, primitive, emotional representation via the central person, or "hero," of the society. It is this system that might produce the republican elite referred to above as the prerequisite to an enduring democracy. It is, furthermore, a modern concept, quite at home in a multigroup society where "human systems engineering" has become a vigorous part of industrial technology. How to implement it presents many a problem now far beyond the capacities of scientists to solve and politicians to apply. By contrast, the notion of a single-faceted representation by a hero is so pow-

erful in the human subconscious and so much easier to implement that throughout history it has achieved a far greater popularity.

## II

### REPRESENTATIONAL SYSTEMS

In order to define a representational system one must first define *representation*, a many-faceted and elusive concept. The term is associated with three quite different meanings: (1) the idea of *mandate*, or instructions; (2) the idea of *representativeness*, that is, resemblance and similarity; and (3) the idea of *responsibility*, or accountability.

The first meaning is derived from private law and belongs to the context of juristic representation, whereas the second meaning is derived from a sociological or existential context according to which representation is basically a fact of likeness

that transcends all voluntary selection (Friedrich 1963, p. 304) and even awareness (unconscious representation; Gosnell 1948, p. 141). In the juristic meaning, we often speak of a representative as a delegate or a mandatory; in the sociological sense we say that somebody is "representative of" to mean that he impersonates (*impersonare*) certain existential features of the group, class, or vocation from which he is drawn. The idea of responsibility and its relationship to representative government, i.e., the third meaning, will be examined below.

To be sure, we are concerned here only with political representation. But political representation cannot be dealt with in isolation from other kinds of representation. It is closely connected with sociological (or existential) representation on the one hand and with juristic representation on the other.

The extent to which political and sociological representation are intertwined can easily be detected in the discussions about electoral systems and *overrepresentation* or *underrepresentation*: a debate that expresses a concern for representativeness and resemblance. Yet the distinction between political and existential representation must be kept firm; otherwise almost *any* political system may claim to be somehow a representational system: ruling groups are always "representative of" the sections or the strata of the society from which they derive.

The extent to which political and juristic representation overlap is shown by the fact that the European theorists of representation—German, French, and Italian—have reached the almost unanimous conclusion that political representation is not "true representation," precisely by using the yardstick of a private law notion of representation (Laband 1876–1882; Orlando 1895; Saripolos 1899; Carré de Malberg 1922; Kelsen 1945). In fact, unless the distinction between political and juristic representation is kept firm, it is only too easy to reach the conclusion that *no* political system can claim to be a really representational system. Yet the distinction between political representation and juristic representation cannot be pushed too far because, among other reasons, political representation is formalized in our institutional arrangements and is part and parcel of constitutionalism.

### Historical development

The emergence of modern political representation from its medieval phase was a gradual process best seen in the political history of England during the second half of the eighteenth century and in the writings of Algernon Sidney, John Toland, and

Humphrey Mackworth. The French Revolution, however, provided a clear-cut break from medieval representation, a fact demonstrated in the constitution of 1791, which expressly forbade mandatory instructions to representatives because the "representatives nominated in the constituencies do not represent a particular constituency but the entire nation." Two subtleties are worth noting. First, by saying nominated *in*, the authors of the constitution expressly meant that the representatives were not nominated *by* their electors; second, the authors deliberately used "nation" instead of "people."

The distinction has far-reaching implications. If the *people* are declared sovereign, the will of the representatives of the people is secondary to the will of a principal (*dominus*), and two wills, that of the people and that of the assembly, are actually postulated. But if the *nation* is declared sovereign—as in article 3 of the Declaration of Rights of 1789—then there is only one will, for the will of the nation is the very same as the will of those who are entitled to speak for the nation (Carré de Malberg [1922] 1962, p. 267).

Thus the origin of the modern idea of political representation was vitally connected with the principle that the deputies represent the will of the nation, not the will of the people. Somewhat paradoxically, members of parliament took on the name "deputies" at the very moment that they ceased to be, properly speaking, deputies. Not only were they declared free agents who should not be given instructions, but they were called to represent a will that did not exist before their own will.

The idea of representation of the nation does not apply only to the origins of modern representation. The prohibition of mandates, sometimes explicitly connected with the principle of the sovereignty of the nation, is affirmed in the nineteenth-century and twentieth-century constitutions of most European countries: Belgium, 1831; Italy, 1848 and 1948; Prussia, 1850; Sweden, 1866; Austria, 1867, 1920, and 1945; Germany, 1871 and 1949; the Netherlands, 1887; and Denmark, 1915. Article 67 of the Italian constitution of 1948 is a good example: "each member of parliament represents the nation and performs his task without being bound by a mandate." And the tortuous formula adopted in the French constitutions of 1946 and 1958—"the national sovereignty belongs to the people"—makes little sense unless one is reminded of the declaration of 1789.

The pattern in the United States may appear to have been different in that no state constitution expressly forbids mandatory instructions. But this omission means only that American constitution framers did not feel the need to state the obvious,

since the United States did not have to break away from a medieval past. Likewise, the fact that the expression "sovereignty of the nation" has no legal meaning in English public law does not imply that British constitutional practice actually abides by a different presupposition. In effect, the French "will of the nation" entrusted to the assembly called for the same founding principle advocated by Burke in his Bristol address of 1774: that the representative should no longer be a delegate but a trustee acting according to his free judgment.

Modern representation reflects a fundamental historical change. Until the Glorious Revolution in England, the Declaration of Independence in the United States, and the French Revolution, representation was not associated with government. Representative bodies were intermediary channels between their mandatories and the sovereign: they represented *somebody* to *somebody else*. But the more the power of parliament grew and the more a parliament was located at the very center of the state, the more representative bodies took on a second function. In addition to representing the citizens, they also ruled over them. Present-day parliaments are Janus-faced: they represent the citizens to the state and the state to the citizens. Clearly, a parliament cannot acquire its modern function, that of governing, without change in its former function, that of representing. A representative body that is inserted into the state must be allowed the discretion that enables it to act for the state. Yet this transformation raises a number of thorny problems.

We are confronted with a puzzling fact: a point has been reached at which a representative body ends by representing somebody (the people, or the nation) to himself. The third party, the one to whom the second party was assumed to represent the first, has disappeared. Moreover, the principal of the representative relationship is hard to identify; for it is not easy to answer the question, *Who* is being represented? According to the constitutional prohibition of mandates and the emphasis on the representation of the *nation*, the representative does not, or should not, represent those who elect him. However, if a representative does not represent his electors, it follows that it is not the election that creates a representative. If this is so, the following question must be faced: Are elections a necessary means for the establishment of a representational system?

### Representation and elections

**Representation without elections.** The query may be stated as follows: Can there be representation without elections? A positive reply is often

given to this question on grounds that are irrelevant to the problem of political representation. If we refer, for instance, to existential or sociological representation, that is, to a mere *fact* of likeness, then it is clear that this kind of representation does not require an election. If representation is defined merely as an *idem sentire*, as the fact of "coinciding in opinion with" (Bagehot 1859), any method of selection or even no method at all might do. What matters is not the procedure that may best secure the coincidence in opinion (and behavior) between the representative and the represented but the existence of such coincidence. Political representation, however, is concerned precisely with securing this coincidence.

Aside from existential representation, one can still point to many instances in which a representative is appointed, not elected—an ambassador, for example. Yet even this case is hardly pertinent, since other guarantees besides the method of selection assure that he will perform his duty qua representative. By contrast, a member of parliament cannot be recalled at will and is subject to democratic control only because he may not be re-elected. The more political representation outgrows juristic representation, the less the former maintains the guarantees provided by the latter—except for the sanction of removal afforded by periodic elections. And this is why the method of selection appears all-important and becomes the peculiar concern of political representation. In principle there can be no representation (other than existential) unless those represented have some say and some way of protecting themselves; otherwise they would be at the mercy of their alleged representative. And since, ultimately, political representation provides only an electoral safeguard, *in this case* there can be no political representation without an election.

**Elections without representation.** The reverse is not true, for we can have elections without representation. Throughout history officials and rulers have been elected, but the election did not in the least imply that the elected represents his electors. This calls attention to the fact that representation is a "think so," in the sense that it is only in terms of "ideas" that a person can be "made present" by another person (Friedrich 1962, p. 164). With the sole exception of the marginal case of existential unconscious representation, there can be no representation unless the representative *feels* the expectation of those he represents, and feels that it is a *normative expectation*. Not only does representation imply "think so," but it is also inevitably linked with an "ought." Therefore, if an election does not explicitly carry with it the meaning and

the intention of electing a representative, not an absolute ruler, no representation follows from an electoral procedure. But this does not prove that elections are not a necessary means: it proves only that they are not, *per se*, a sufficient means.

**Elective representation.** Elections are one thing, and representation is another. Still, modern political representation is "elective representation," for it is precisely this combination that makes representation both *political* and *modern*.

The means (elections) cannot surrogate the animus (the idea of representation), but the animus by itself does not suffice. Nonelective representation—"virtual" representation in the vocabulary of Burke—needs the support and the safety of "actual" (electoral) representation.

Let it be emphasized that this conclusion applies *only* to political representation (not to juristic and even less to existential representation) and especially with reference to securing responsibility. The electoral theory of representation actually is the theory of responsible and responsive representation; it is not concerned with satisfying the requirement of similarity but with securing the obligation to respond. [See ELECTIONS.]

### Representational systems defined

**Conditions.** We may now attempt to reply to the question, What *is*, and what *is not*, a representational system? A survey of the literature indicates wide disagreement, for it would seem that *any one* of the following conditions is either sufficient or necessary:

(1) The people freely and periodically elect a body of representatives—the electoral theory of representation.

(2) The governors are accountable or responsible to the governed—the responsibility theory of representation.

(3) The governors are agents or delegates who carry out the instructions received from their electors—the mandate theory of representation.

(4) The people feel the same as the state—the *idem sentire*, or syntony, theory of representation.

(5) The people consent to the decisions of their governors—the consent theory of representation.

(6) The people share, in some significant way, in the making of relevant political decisions—the participation theory of representation.

(7) The governors are a representative sample of the governed—the resemblance, or the mirroring, theory of representation.

According to the previous discussion, conditions 1 and 2 are joint conditions. The mere occurrence of elections does not indicate, in itself, a repre-

sentational system; accountability to the people is a mere phrase if it cannot be enforced by the sanction of electoral removal. Condition 3 either refers to the premodern practice of representation or appears too exacting and impracticable. On the other hand, conditions 4, 5, and 6 are, *per se*, too vague. It is only too easy to presume consent and *idem sentire*; participation may well be obtained by manipulation and regimentation. It can be said, therefore, that these three conditions are more a consequence than a premise; they refer to something that is likely to be found *in* a representational system but not to a founding condition of a representational system. As for condition 7, the requirement of representativeness is an additional, not a necessary, requirement, which depends very much on the electoral system that is adopted.

**Responsibility and representativeness.** Nobody denies, to be sure, that one is likely to feel better represented if the representative is somebody "like himself," that is, like-minded, somebody who acts the same because he is (existentially, or vocationally) the same. While this explains the recurrent quest for a parliament that is related to the society (as Mirabeau said) like the map to the territory it represents (for example, Ross 1955, p. 51), the unfortunate thing is that one may conceive of a parliament that is a perfect mirror and yet does not perform a mirroring function. This is why accountability takes a procedural precedence over resemblance, at least in politics.

The argument can be pursued: even if representativeness is not, by itself, a sufficient condition, it can still remain a necessary requirement. The difficulty is, however, that while responsibility and like-mindedness are easily combined in a one-to-one relationship, they are very difficult to combine in a many-to-one relationship (when the many amount to tens and even hundreds of thousands). In the context of political representation we are, therefore, confronted with a dilemma: either we sacrifice responsibility to representativeness, or we sacrifice representativeness to responsibility. This conclusion needs to be qualified, however, and calls for a closer look into the notion of responsibility.

The idea of responsibility has two sides, or implications: (1) the *personal* responsibility to someone, that is, the obligation of the representative to answer to the principal and (2) the *functional* or technical responsibility of meeting given standards, such as capable and efficient conduct or the "right" course of action (Friedrich 1963, pp. 310-311). The first is a *dependent* kind of responsibility; the second is an *independent* responsibility. In the first sense, the representative is related to

somebody; in the second sense, reference is made to his "responsible conduct," thereby implying that the behavior of a representative is basically entrusted to his own conscience and competence.

When the distinction is translated into political terms, it appears that the expression "responsible government" covers two different expectations: (1) that a government is responsive and accountable to the people for what it does and (2) that a government behaves responsibly by acting efficiently and competently. We may call the first a *responsive* government and the second an *efficient* government. And the difference between the two is no small difference.

In our private dealings it matters little whether we lean more on personal or on functional responsibility, for in either case the representative has only one end in view: the sole interest of the principal, whatever happens to any other interest. But when political representation is concerned, another end is at stake: the interest of the whole, whatever happens to private interests. For this reason, the distinction between dependent and independent responsibility is, in politics, a crucial distinction, and it matters very much which kind of responsibility a representational system leans on. It is precisely on account of its independent margin of functional responsibility that a government is empowered to pursue the interest of the whole against partial and partisan interests. The more that independent responsibility gives way to dependent responsibility, the more likely it is that the general interest will give way to the claims of sectional, short-sighted, and contradictory interests.

It is not a paradox, then, to say that a responsible government can also be a very irresponsible government. Actually, the more responsive it becomes, the less it is in a position to behave responsibly. Ultimately, a choice must be made between the representativeness and the efficiency of government. We cannot ask a government to do one thing and its very opposite, that is, to yield to the demands of the governed and resist the "irresponsible demands" of the governed. More exactly, we cannot have, at the same time, *more* responsiveness and *more* independent responsibility. [See RESPONSIBILITY.]

### Types of representational systems

The foregoing explains why representational systems belong to two main patterns originating in England and France. The English type of representational system is based on a single-member plurality system of electoral representation, which affords little electoral choice and favors, therefore,

a two-party system; whereas the French type is based on proportional systems of electoral representation, which afford a large electoral choice and thereby facilitate multiparty systems. The English type sacrifices the representativeness of parliament to the need of efficient government, while the French type sacrifices efficient government to the representativeness of parliament.

If the vocabulary of politics were updated, the English type of representational system could fittingly be labeled "cabinet system" and the French type could properly be called "parliamentary government." Whatever the terminology, "representative government" poses a two-sided problem: governing and representing. The English (and American) type of political system maximizes the governing requirement, whereas the French (and Continental) type has maximized the mirroring requirement.

To be sure, in a number of countries one finds a more balanced combination of efficient government and representative representation (for example, the countries having both proportional representation and a relatively limited number of parties, say from three to five). Nonetheless, from the viewpoint of institutional engineering the fact remains that we cannot build a representational system that maximizes at one and the same time the function of functioning and the function of mirroring. There is a point at which we must choose, and the realistic alternatives are independent or dependent responsibility, rather than governed and governing democracy (Burdeau 1949-1957, vol. 6), or feigned and veritable self-government (Ross 1955, pp. 50-51).

The more developed and differentiated representational systems of the Western nations do not exhaust the range of all possible representational systems. Yet to the extent that the political structures of the developing nations are of a derivative nature, these nations are likely to be confronted with the issues and the problems that we have been discussing. The experience of the West does provide, therefore, a parameter for stating the minimal requirements for the existence of any representational system.

A representational system cannot materialize unless electoral accountability makes the governors responsible to the governed. However, all that is required is personal or dependent responsibility, since functional or independent responsibility qualifies the performance, not the relationship. Even the requirement of dependent responsibility should not be taken too literally; it merely implies *responsiveness*, albeit a sanctionable and safeguarded responsiveness.

In conclusion, a political system qualifies as a representational system whenever honest electoral practices secure a fair amount of responsiveness of the governors to the governed. This does not necessarily imply a large enfranchisement; but it does imply that no representational system can be based merely on "virtual representation." Nor does a political system qualify as a representational system if it has one ruler (monarch or dictator) who monopolizes the claim of representing the whole. Unless the representative function is entrusted to some collective body that is free enough to express a diversity of views and interests, we may be confronted (at least existentially) with representative rulership but not with a representational system.

### Contemporary issues

**Scale and scope of representation.** When representational systems were introduced in England and on the Continent, the electorates were small and so were the governments. With the passing of time the electorate has grown from a few hundred to tens of thousands of electors for one representative. Correlatively the small government with simple problems and few functions has become a large government with complex problems and innumerable functions. Both developments combine to place an ever-growing strain on the relational aspect of representation, that is, on the link between those represented and their alleged representatives. As Bruno Leoni put it, "... the more numerous the people ... one tries to 'represent,' ... and the more numerous the matters in which one tries to represent them, the less the word 'representation' has a meaning referable to the actual will of actual people other than that of the persons named as their 'representatives'" (1961, p. 18).

While political representation has always been a many-to-one relationship, the many have become so numerous that one may well wonder if, in a 50,000-to-1 ratio, it still makes sense to say that each person is represented. The reply is related to the scope of representation and of representative government. As long as representation is considered basically a protective device that limits (among other things) the scope of government, the reply is still, "Yes, it surely makes sense."

But the wider the coverage and the larger the area of intervention that calls the representative to decide upon matters that fall beyond the understanding of the represented, the more one may be alarmed by the potential of arbitrariness that is involved and wonder whether the scope of representation can be stretched without end. At any rate, one can hardly escape the feeling that the

initial link in the chain, the represented, has become an infinitesimal quantity.

**"Who" is represented?** The problem may be stated as follows: The larger the size of the electorate, the smaller the scale of representation; and the smaller the scale of representation, the more we lose sight of *who* is being represented. At least, this seems an inescapable conclusion if the *who* of representation refers to the "individual."

While this conclusion is not always acknowledged in this form, it helps to explain the dissatisfaction with the individualistic or atomistic basis of the theory and practice of representation. The opposition to "individualistic representation" need not be explained as merely a nostalgic revival of medieval corporate representation. However, the fact is that whenever the anti-individualistic mood has prevailed (as in Italy and Germany during the 1930s), it has been used to justify an autocracy rather than to suggest new means or techniques of nonindividualistic representation.

Without abandoning the starting point of the "individual voter," we may scrutinize his voting behavior with reference to the representational message, or intention, that he transmits. It has been suggested that the act of voting expresses (1) what the elector *has to say* (or thinks), or (2) what the elector is (existentially), or (3) what the elector *wills*. According to the first view, representation represents opinion; according to the second, it represents class or vocational appurtenance; according to the third, an individual may be represented even though he is inarticulate or silent.

The first is the traditional view, and is apparently destined to succumb under the joint blows of electoral numbers and big government. Whether we like it or not, we are thus likely to fall back on the other two interpretations. Both make the individual voter *less* of an individual. For if we vote by identifying ourselves with a social class, the fact that we vote per capita does not mean that we vote qua individuals. And the "will theory" of representation not only can be conceived collectivistically but can, moreover, be put to use for any purpose whatever, since a will that is silent or not articulated can be said to wish anything that its interpreter thinks it should.

These two approaches provide a way out precisely because they no longer attempt to answer the query concerning *who* is being represented. They actually provide an answer concerning *what* is being represented—which is not quite the same thing.

**"What" is represented?** Since all representational systems adopt a territorial criterion of elec-

toral apportionment, what is actually being represented are the localities, the geographic areas. But acknowledgment of this only leads to a reformulation of the question, What comes to be represented through a territorial channeling? The reply is largely a matter of speculation (or of needed research), except for one definite conclusion: territorial representation does not satisfy and even impedes occupational or functional representation.

The question of what is being represented can also be approached by discussing whether representation is focused more on ideal preferences or on material interests, more on values or on wants. And while territorial representation considers the citizen (not the *homo economicus*), thereby implying, among other things, that the voter should be encouraged to respond in terms of ideals rather than wants, the contention is that the adoption of vocational representation would definitely elicit a response in terms of material interests. In any case it should be pointed out that whether or not we believe in "individualism," and whether or not territorial representation works as it is supposed to work, we are made to vote qua individual citizens according to a territorial criterion of apportionment because it is the safest way of getting the electoral business done. If territorial apportionment is already exposed to tricky manipulations ("gerrymandering"), vocational or any other kind of functional apportionment would allow no end of manipulative trickery. [See APPORTIONMENT.]

In free societies, the idea of replacing a political parliament with an occupational parliament (or parliament of experts) has only led to attempts to combine the two. Side by side with the political parliament, some kind of technical or vocational parliament was established expressing the views of special interests, for example, the *Reichswirtschaftsrat* of the Weimar Republic and the economic advisory councils established in the 1950s in Italy and France (but not in West Germany). The attempt has definitely failed in Italy while it has been relatively successful in France and in some smaller countries. Ultimately, however, great difficulties arise out of the relative positions of the technical and the political parliaments. There are three possibilities: either (1) the technical parliament has the final say, or (2) the two parliaments are made equal, or (3) the technical parliament is a subordinate consultative body. The first case would in effect eliminate the political parliament; the second would lead to systematic conflict and paralysis; whereas in the third instance the consultative body would be listened to only when the political parliament was in the mood to do so.

What is being represented, then, in or by a political parliament? Local and community interests, class appurtenance, special and sectional interests, ideals, individual wants? Depending on the scale of representation, different combinations of all of these are represented. All sorts of voices that are strong enough to make themselves heard somehow find their way to a representative body.

The "how" of representation. Whatever the "who" or the "what" of representation, there remains the problem of the "how." And, clearly, the how of representation feeds back on the what and even on the who.

Broadly speaking, the how refers to the way in which a representational system is established and made to operate. Precisely who and what benefits from a given representational system may remain obscure, but one thing is clear: if the how is known, a system of elective representation (as defined above) allows more freedom and provides more responsiveness than any other known system.

More specifically, the how of representation can be taken to mean the style of representation, as Wahlke and his associates (1962) call it. In this sense the how of representation is related to the role orientations of the representative, for example, whether he acts more as a delegate or more as a trustee or whether he is more a party man, a constituency servant, or a mentor (Eulau 1962).

From another point of view, the how of representation is related to the electoral system and to the party system. The relationship between electoral systems and representational systems has already been mentioned and is a relatively old problem (for example, Duverger 1951). A more recent problem is how the representational process is affected by party interposition. For the more mass democracy there is and the more mass parties there are in a political system, the more the how of representation hinges on the party system as a vehicle of the representational process.

Party representation. The scale of representation being as it is, parties are a means for reducing unmanageable numbers to a manageable size. Citizens in modern democracies are represented *through* and *by* parties. This seems inevitable. The troubling thing is, however, that a point may be reached, or even has been reached, at which, as Beer (1965, p. 88) concisely put it, "the function of representing the national interest, once attributed to the Sovereign and later to Parliament, is now performed by party. Party—to echo Herman Finer's phrase—is indeed 'king.'"

Now, to speak of the party as a "filter" for political representation is one thing; to speak of the

party as "king" is quite another thing. The theoretical and constitutional problems that have resulted from this development are thorny; this is one of the reasons why even the more recent constitutions avoid giving formal recognition to party representation (the exceptions are the constitution of Brazil, the Bonn constitution, and the French constitution of 1958).

A realistic view of the present-day representational process confronts us, then, with a two-step process or even with a process that is cut in two: a relationship between the electors and their party, and a relationship between the party and its representatives. And the contention is that party nomination, that is, party co-optation, tends to be the real election; for while the electors choose the party, the elected are actually chosen by the party.

Of course parties, party systems, and countries are very different, and therefore generalizations can be very misleading. Yet it can be argued that whenever we are confronted with rigidly and powerfully organized mass parties—as is usually the case in Europe—the representative is likely to be far more a spokesman for his party than for anyone else (including his electors), and party bonds are perhaps far stronger than any other bonds (including the ties of social class). Thus, according to Duverger (1956), the modern representative is entrusted with a "double mandate," from his electors and from the party; and in practice the party mandate takes precedence over the electoral mandate.

Representation has lost all immediacy and can no longer be viewed as a *direct* relationship between the electors and the elected. The process hinges on three elements—those represented, the party, and the representatives. And the intermediary link appears to be so decisive that a point could be reached at which parliamentary representation would "resemble" party personnel, in the strict meaning of party career men, much more than the society it was asked to resemble. If so, the party would indeed be king and one could conclude that the *who* being represented is actually the party. In spite of the lack of adequate research, the available evidence suggests that this point has not yet been reached, although the parliamentary duplication of professional party politicians is progressing. [See PARTIES, POLITICAL.]

Although not unusual, it is perplexing that while actual political developments point in one direction, much of the prevailing theory and practice point in another. The scale of representation has become infinitesimal; the scope of representation

bypasses the grasp of the common man; furthermore, parties have largely replaced the electorate in deciding what should be represented and how. All these developments seem to indicate that what is really at stake is "responsibility" and that the real problem is how to improve the performance of big government in terms of independent responsibility without too great a loss of accountability. Yet much of the recent literature still emphasizes the sociological approach to representation, and proportional representation still enjoys the reputation of being the one truly representative electoral system. Since both concerns imply "similarity," or representativeness, they could be described as somewhat anachronistic.

### Research issues

To the extent that representational systems are normative constructions, they are largely beyond empirical disproof. Representational systems also presuppose, however, factual assumptions that can, and should, be tested empirically. In this connection there are three main areas of inquiry that are relevant to the theory of representation: (1) public opinion, that is, what people really want and expect; (2) decision makers, that is, who is actually chosen (how) to serve as a representative; and (3) representational behavior [see REPRESENTATION, *article on* REPRESENTATIONAL BEHAVIOR].

Despite field surveys and opinion polls, we do not know as much as we should concerning what people really demand from a representational system. According to one author, "the English people still like being governed," and the evidence suggests that the order of priorities is, for the British, the following: (1) consistency, prudence, and leadership; (2) accountability to Parliament and the electorate; (3) responsiveness to public opinion and demands (Birch 1964, p. 245). Possibly this could also be the order of priorities in West Germany, while perhaps in the United States responsiveness ranks second. On the other hand, one might guess that in countries like France (during the Third Republic and Fourth Republic) and Italy, the order of priorities would be (1) responsiveness, (2) accountability, and (3) leadership (that is, independent responsibility). So far, the results of only one nation-wide study are available and they concern constituency influence in the U.S. Congress (Miller & Stokes 1963).

As to the second focus of inquiry, decision makers in the legislative arena, there is growing documentation concerning *who is who* in parliaments (Meynaud 1967). While the data are very uneven and difficult to compare, we are now in a

position to test at least some aspects of the "resemblance" theory of representation on a country-by-country basis: England (Guttsman 1961; Berrington & Finer 1967), France (Dogan 1961; Hamon 1967), United States (Matthews 1954a; 1954b; 1967; Miller & Stokes 1965), Italy (Sartori 1957; 1967), Israel (Akzin 1967).

The sociological approach to representation that is implied by the foregoing documentation is seldom focused, however, on the problem of party representation: for example, the parliamentary duplication or projection of party career personnel has as yet received very little attention. In general, the role of the party as an intervening variable has remained a neglected area of research. The findings on whether (and if so to what extent) it is the party that administers the sanction of removal, or on whether the party is the real recruiter, are poor, peripheral, and widely conflicting (for example, Seligman 1958, p. 361; Sorauf 1963, p. 120). Likewise, the claim that parties receive an "electoral mandate" remains a matter of speculation, even though it could be warranted or disclaimed by ascertaining whether this is really the expectation of the voter.

The resemblance aspect of representation has been explored far more than the aspects of accountability and responsibility. Possibly research in that area is easier. This is all the more reason for stressing that a reorientation of the focus of research on accountability is badly needed. For instance, whose sanction of removal is feared most—the sanction coming from the electorate, from the party machine, or from other supporting groups? This is a rather crucial question—and a question that remains unanswered.

#### BIBLIOGRAPHY

A penetrating analysis of the issues raised by political representation in the context of Continental constitutionalism, with particular reference to France, may be found in Carré de Malberg 1922. Sartori (1957) 1962 includes a survey of the literature; Birch 1964 covers the British approach; and de Grazia 1951 is relevant for the American pattern. Concerning the medieval origins of representation, Clarke 1936 is still a valuable analysis, in addition to the classic Carlyle & Carlyle 1903–1936. With reference to the European constitutional development of the theory of representation, the most influential work has been Gierke 1868–1913.

## III

## REPRESENTATIONAL BEHAVIOR

Representational behavior refers to that aspect of legislative conduct that is studied for the nature, extent, and basis of its correspondence with constituency opinions. Representatives are assumed to differ in the extent to which they reflect their constituents' opinions in their legislative activities, most notably in their decision making. The modern student of representational behavior is interested in (1) determining the extent of agreement between constituency opinion and legislative behavior on various issues, (2) accounting for differences observed in the relationships between representatives and their constituencies, and (3) specifying the effect of different representative-constituency relationships upon public policy formation.

The study of the representational behavior of individual legislators is particularly important in political systems where party voting is not essential for governmental stability. In a parliamentary system featuring well-disciplined parties and slim majorities, most notably the modern British Parliament, individual representatives are subject to restraints on their voting behavior that are unknown in other legislative bodies, such as the United States Congress, where members are relatively free to vote their opinions or to respond to political forces other than the party leadership. Although eighteenth-century Britain can be credited with the birth of interest in representative-constituency relationships, the United States has produced the most extensive research on the topic. In Britain, within the last century, the motivations for research on representational behavior apparently decreased as party voting increased in parliament.

**Development of interest.** The study of representational behavior and representative-constituency relationships assumed importance with the development of representative democratic government. Democratic theory held that the general public ought to have some participation in governmental policy making so that the government would do what the people wanted it to do (or at least did not do what they did not want). All modern democracies eventually developed some form of representative government, which institutionalized popular participation in governmental policy making

through popular election of representatives empowered to formulate governmental policy. The establishment of a popularly elected legislative body did not, however, insure that governmental policy would follow public opinion. Once elected, the representatives might or might not satisfy popular desires in formulating public policy.

Viewed strictly from the standpoint of democratic theory, it was undesirable for representatives to act contrary to public opinion. But at the same time, it was obvious that complete reliance upon public opinion in governmental policy making was also likely to have undesirable consequences. The voters' ignorance or misunderstanding of the facts involved in the issues, their inclinations toward selfishness in promoting their own interests, and their tendencies toward hasty and ill-considered actions were cited as factors that would lead to unwise or unjust governmental policies if the representatives were merely to act in accordance with their constituents' wishes.

On one hand, then, both abstract requirements of democratic theory and practical consequences of making representatives directly accountable to the people urged a close correspondence between constituency opinion and legislative behavior. On the other hand, both abstract notions of desirable government and practical necessities of rational decision making argued *against* a close correspondence between them. The conflict between these considerations was of concern to scholars who sought to evaluate the operation of representative government. This conflict provided the initial interest in the study of representational behavior.

Those who were interested primarily in evaluating the operation of representative government sought to determine the proper relationship between the representative and his constituency. Later students who were less interested in the evaluative aspects of political science were also less concerned with determining the "proper" relationship between the representative and his constituency. They sought instead to clarify types of relationships, discover the factors associated with different relationships, and predict the probable consequences of different relationships for public policy.

**Early approaches.** Edmund Burke's defense of his voting record in his classic "Speech to the Electors of Bristol" in 1774 set forth a conception of the proper role of the representative as one who ought to respect his constituents' opinions, who ought to prefer their interests above his own, but who ought *not* to sacrifice his unbiased opinions in deciding for the good of the whole nation

(quoted in de Grazia 1951, p. 38) [see BURKE]. Burke's often quoted statement most certainly influenced the subsequent study of representative-constituency relationships. Inquiry into the topic commonly raised the general question to which Burke addressed himself: What ought to be the relationship of the representative to his constituency? This question elicited normative prescriptions but did not invite empirical inquiry, and the literature that developed was characterized by opinions and arguments concerning the proper role of the representative. In general, extreme democrats (e.g., the Levellers of seventeenth-century England and the "direct democrats" in the early twentieth-century United States) insisted that the representative ought to obey the wishes of his constituents, while those less enamored with the unqualified application of democratic principles argued that better legislation would result if the representative relied mainly on his own judgment when deciding upon legislation.

Interwoven with the question of whether the representative ought to obey the wishes of his constituents or vote according to his own judgment was another question: Ought the representative to be guided in his decisions by the welfare of his constituency or the welfare of the state as a whole? The logical independence of these questions was not always recognized in the polemics concerning the proper role of the representative. The distinction between the two questions has recently been acknowledged and labeled as a difference between the "style" and the "focus" of representation (Wahlke et al. 1962, p. 269).

The style of representation refers to the particular criterion of judgment the representative ought to use in deciding on legislative issues. The basic argument over the proper style of representation was whether the representative ought to behave as a "trustee" and arrive at decisions either on the basis of his own sense of right and wrong or on his personal evaluation of the facts or whether he ought to behave as a "delegate" and disregard his personal opinions while executing those of his constituents. (It should be noted that the trustee-delegate terminology is not standard in the literature. Some writers have reversed the application of the terms or substituted other labels, such as "agent" or "ambassador," for those given here.)

The focus of representation refers to the particular group of persons whose welfare the representative ought to consider in deciding on legislative issues. The basic argument over the focus of representation was whether the representative

ought to be "district-oriented" and consider primarily the welfare of his constituents or whether he ought to be "nation-oriented" and consider the welfare of the nation as a whole.

Argument over the normative question of how the representative ought to act characterized the literature on representative-constituency relationships from the second half of the eighteenth century to the middle of the twentieth century. Like many other "ought" questions in political science, the question of the proper role of the representative defied definitive answers. The answer to this question involved more than reasoned appeals to value positions concerning what constituted good government. Vital information was lacking on empirical aspects of representative-constituency relationships, such as the nature and extent of the constituents' knowledge of legislative issues, the ways by which the constituents' opinions on issues were communicated to the representative, the correspondence between his perceptions of constituents' opinions and their actual opinions, the politics of his district, and so forth. It became obvious that detailed knowledge of these and other factors was not only important in its own right but was also essential for those who remained interested in the classic normative question.

**Recent developments.** Modern research in representational behavior has been characterized by its concern for empirical questions, but research to date has been handicapped by the unavailability of certain behavioral and psychological data required for an adequate understanding of the subject. In order to determine the faithfulness with which representatives represent their constituents' wishes, for example, data are needed both on the behavior of incumbents and on the opinions of their constituents. In general, relevant data on the representatives' behavior has been more accessible than matching data on their constituents' opinions.

Research on representational behavior has been aided by the ready availability of public information about important aspects of the incumbents' behavior, such as votes cast on the floor and sponsorship of bills. Information on other legislative activities, such as speaking on proposed bills, may also be found in published sources or observed directly. Behavior in committee meetings, party conferences, or outside the legislature proper is less easily learned but may be determined through interviews with representatives or other participants in the political process. Despite the wide variety of legislative activities that could have relevance for the disposition of public issues on which constituents have opinions, studies have generally relied

solely on the representative's floor votes for the data on his side of the relationship. Although some doubts have been raised concerning the wisdom of relying on the recorded floor vote as the sole indicator of the representative's behavior, there seems to be little question that floor votes do constitute important data. In legislative bodies that feature strong party voting, however, some aspects of a representative's activities other than his floor votes would probably be more suitable for research.

The overriding research problem has not been obtaining data on representatives' behavior but on constituents' opinions. The sample survey is the most suitable research technique yet developed for obtaining reliable information about the distribution of personal opinions among populations. An appropriately drawn sample of about 2,000 respondents furnishes an adequate basis for making confident statements about the distribution of voters' opinions in the United States. But the science of probability sampling is such that a sample of practically the same size is needed to make statements at a similar level of confidence about a population of only 400,000—about the size of the average congressman's constituency in the United States. Because careful sample surveys are expensive to conduct and complex to administer, survey techniques until very recently have not been used at all for systematic research in representational behavior.

A pioneering effort was undertaken in 1958 by the University of Michigan's Survey Research Center, which designed its national sample of the United States electorate in a manner that permitted limited analysis of constituency opinions in about one hundred congressional districts (Stokes & Miller 1962). That effort opened the door for a genuine breakthrough in the study of representational behavior, enabling the first direct comparisons to be made between representatives' behavior and their constituents' opinions (Miller & Stokes 1963). Much additional work remains to be done with this approach, however, before firm generalizations can be made concerning the interesting empirical questions of representative-constituency relationships. It is unlikely that these generalizations will soon be formulated, for cost and complexity factors involved in sampling a number of constituencies still obstruct the development and application of this methodological approach.

Without the use of sample survey methods, students of representational behavior have conducted their research by classifying constituencies according to social characteristics on which census-type data were available (such as occupation, per cent

urban, per cent native-born, and so on) and then correlating these characteristics with the voting positions of their representatives. In some cases, researchers have attributed opinions to the inhabitants of certain districts on the basis of their social composition: constituents in working-class districts were said to favor unemployment guarantees, those in farming districts were said to favor agricultural subsidies, and so forth. In other cases, this somewhat risky imputation of opinions has been avoided, and researchers have simply examined similarities and differences in the voting patterns of representatives from various types of districts. A common refinement of such research involved introducing the variable of party competition in the district and analyzing legislators' votes according to the "safe" or "doubtful" nature of their constituencies as determined by past election returns.

Studies of roll call voting in the United States Congress and in American state legislatures have disclosed tendencies for representatives from different types of districts to vote on certain measures in accordance with presumed or imputed interests of their constituencies. The strength of these tendencies appears to increase with an increase in homogeneity of the social composition of the district. Those representing districts composed almost entirely of working-class people, for example, tend to give more support to legislation establishing unemployment guarantees than those representing districts dominated by working-class people but with substantial white-collar elements. Nevertheless, constituency characteristics have been shown to account for only a part of voting behavior in American legislatures. The representatives' party affiliations generally stand out as the most pervasive influence on voting alignments, despite the undisciplined nature of American parties. The importance of party affiliation is so clearly recognized that researchers often attempt to measure constituency influences on voting by examining the instances when representatives abandon the party position. When the party's position on an issue coincides with the position assumed to be favored by the constituency, the representative's vote is unlikely to be contradictory. When the party's position and the assumed constituency position are in conflict, his vote is less predictable. There is some evidence to indicate that a representative will tend to favor the presumed interest of the constituency in case of such conflict if he comes from a "doubtful" rather than a "safe" district.

Students of representational behavior who have made use of census-type data on constituency characteristics in lieu of sample survey data on consti-

tuents' opinions have produced these and other suggestive findings. But they have not been able to answer some of the most important empirical questions because they have lacked reliable knowledge about the nature and distribution of constituency opinions.

In the absence of survey information about constituents' preferences, the exact impact of constituency opinions on representational behavior cannot be measured. Not only is the researcher unable to establish the extent to which the legislator's behavior conforms to constituency opinions, but he is also unable to determine how closely the representative's personal attitudes and perceptions match these opinions.

**Research needs.** The two basic types of data required for research in representational behavior are, for reasons mentioned above, data on constituency opinions and data on representatives' behavior. At least four other categories of information, which remain to be discussed, are especially important for the study of representational behavior. Data are needed on representatives' personal attitudes toward policy issues, the motivational bases of their behavior, their perceptions of their constituencies, and representative-constituency communications. Each of the last four categories will be discussed in turn.

*Representatives' personal attitudes.* In general, students of legislative behavior have shown that a representative's voting record reflects, to some extent, his personal attitudes as determined by independent attitude tests. Representatives whose voting behavior suggests that they are especially attuned to the opinions of their constituents may in fact exert little or no effort to ascertain district opinions and may merely vote according to their own personal attitudes. Their votes, however, may conform closely to their constituencies' positions simply because they hold the same basic attitudes and values as their constituents. The mechanics of representation operating in this situation are quite different from those involved when a close correspondence between constituency opinions and voting behavior exists regardless of the representative's personal attitudes toward the issues. Shifts in constituency opinions over time are more likely to be reflected in the representative's behavior when he is consciously responsive to those opinions. In order to assess the operation of constituency control over a representative's behavior, it is necessary to know something of his personal attitudes toward the issues on which he votes.

*Motivational bases.* In order to understand why a representative acts in a given way, it is necessary

to give explicit attention to the motivational forces guiding his behavior. Scattered attention has been given to motivational factors in case studies of legislative decisions, but this obviously important variable has been largely ignored in more comprehensive studies of legislative behavior. Undertaking motivational explanations of human behavior may appear to be hopelessly complex. But complexity can be avoided and the understanding of representational behavior can be helped considerably if some simple motivational concepts are introduced into the analysis. Three different motivational bases seem to be particularly relevant to the study of representational behavior. The representative's behavior might be guided by a desire to (1) express his own personal attitudes toward the legislation before the chamber, (2) fulfill his personal conception of what the proper representative *ought* to do (e.g., act as a delegate or a trustee), or (3) be re-elected to office at the next election. Probably no representative's behavior is completely guided by any one of these three motivational bases, and more than one base may underlie any given act. There undoubtedly are other important motivational bases. The point is, however, that the study of representational behavior will remain incomplete unless explicit attention is given to the collection and analysis of data relevant to the motivational bases of political conduct.

*Representatives' perceptions of the constituency.* A person's reactions to a situation depend on how he perceives it, and his perceptions do not necessarily accord with reality. It is important to determine the accuracy of the representative's perceptions of his constituents' opinions on various policy matters. The representative who consciously tries to vote in accordance with his constituents' opinions, but who frequently misreads them, may seem to be ignoring his district when in fact his behavior is due to a failure in communication instead of a lack of concern for constituency opinions.

It is also important to gather information on the representative's perceptions of the important political forces in his district, which can affect his chances for renomination or re-election. These forces may exert themselves at either stage, depending on the structure of politics in the district. They may, for example, be important at the nomination stage, where the official party endorsement is acquired. In some cases, the representative himself may control his own renomination through his domination of the district party organization. (This situation is not uncommon in the United States but perhaps occurs less frequently in countries with

stronger national parties.) In other cases, effective control at the nomination stage may lie with a small group of party leaders, whom the incumbent must court in order to be renominated. Finally, where the nomination is won through elections at a party primary or in conventions, there is the possibility that a large number of party workers or rank-and-file voters may be the force to be courted.

The importance of the general election stage as an obstacle to re-election depends on the tendencies toward party voting in the district. In districts that are safe for one party, failure to be renominated constitutes the only real threat to re-election. In competitive districts, the key to victory may involve cultivating support among various groups of voters. A candidate is not likely to be unaware of these obvious political facts, but because of his closeness to the situation or because of his anxiety over re-election, he may perceive them somewhat differently than an outside observer.

Data on the representative's perceptions of the district's politics are important for understanding his reactions to constituency-based demands, especially if he is strongly motivated by a desire for re-election. Data on the legislator's perceptions of his constituents' opinions have broad utility for the study of representational behavior but are especially important if the representative is strongly motivated to do what his constituents want, for then his behavior depends on how he perceives those wants.

*Representative-constituency communications.* The representative's perceptions of his constituency are affected by the content of the messages he receives and by the manner of their transmission. A useful distinction can be made between representative-initiated and constituency-initiated communications. The representative may himself try to determine the opinions of his constituents by examining the local newspapers, conducting his own public opinion polls, or circulating among the voters in his district. The amount of effort he expends in initiating communications with his constituents, the types of communication activities employed, and the specific constituents or constituency groups contacted can be expected to depend on the motivational basis of the representative's behavior and on his various constituency perceptions.

Constituents may also initiate communications to their representatives by such means as writing letters, sending telegrams, and making personal visits. Studies have shown that the opinions conveyed through various forms of constituency-initiated communications are unlikely to be accurate reflections of the distribution of constituency opinions due to the operation of distorting influ-

ences. For example, representatives are more likely to hear from those who agree with them than from those who disagree, and letters are more likely to be written in opposition to proposals than in support of them. Those who do initiate communications also tend to rank higher in education, income, political involvement, and occupational status than those who do not.

Sources of distortion are also present in representative-initiated communications. Legislators tend to communicate more with those who agree with their views, who are more highly involved in politics, and who share the same party identification. Although faithful disclosure of constituency opinions can be produced by professional polling or survey research organizations, few representatives can afford such expensive means of acquiring this information. Lacking essential technical and organizational resources of professional research firms, those who engage in opinion polling seldom develop accurate knowledge of constituency opinions because of sampling difficulties or biased wording of questions. The fact is that some representatives are relatively unconcerned about the accuracy of their polling procedures, for they frequently conduct polls for purposes of public relations with little intention of studying the findings for decision-making purposes.

Whether representatives poll their constituents for public relations or for decision-making purposes probably depends, once again, on their perceptions of the constituency and on their motivational basis of behavior. A delegate-styled representative, who is motivated primarily by a desire to perform his representational role by voting the way his constituents want, would probably strive for greater accuracy in polling and give more consideration to poll findings than would, for example, a trustee or a representative from a safe district whose chances for renomination are controlled by a group of party leaders. But regardless of the motivational bases of the representative's behavior, detailed information concerning the persons, groups, messages, and media involved in communications constitutes another important category of data for the study of representational behavior.

### RESALE PRICE MAINTENANCE

In the practice of resale price maintenance the manufacturer determines and enforces the price at which distributors resell his product. Hence, resale price maintenance is also known as vertical price fixing, as price protection, or as the practice of imposed prices. The term "fair trade" is an American euphemism. A manufacturer may set resale prices for either or both the wholesale and retail stages of distribution, and the prices may be fixed prices or minimum prices.

The practice is confined largely to branded goods but is also found in unbranded products such as various building materials (for example, in the United Kingdom). Among branded goods, resale price maintenance is or has been associated with drugs, proprietary medicines and toilet preparations, books and magazines, phonograph records, domestic electrical appliances, furniture, motor vehicles, tobacco products, liquor, confectionery,

and office equipment. (The difficulty of controlling trade-in allowances has made price maintenance less effective in consumer durables.) The extent of the practice and the products involved differ greatly from country to country, being much affected by legal provisions. In the United Kingdom, where resale price maintenance has been extensive, it affected, at its peak, one-fifth or more of total consumer expenditure; in the United States the present proportion probably is well below 5 per cent.

**Effects on distributive trades.** Resale price maintenance, when it covers the bulk of a particular branch of trade, has the following effects on retailing (or, *mutatis mutandis*, on wholesaling): It eliminates or attenuates retail price competition, and it tends to make gross margins (the difference between selling prices and buying prices) and retail prices higher than they would be otherwise. Studies of the history of resale price maintenance and of its removal support this conclusion, as do statistical studies of prices in comparable states of the United States with and without price maintenance.

The removal of price competition directs retail competition into nonprice channels: the struggle for customers takes the form of the competitive extension of retail services, reflected in more expenditure on inventories, sales staff, provision of credit, amenities, and location. Nonprice competition tends toward a greater geographical dispersion of retail outlets and sustains a larger labor force in distribution. Competition of this kind ensures that the higher gross margins do not mean higher net returns on capital in retailing.

Resale price maintenance also tends to retard innovation and change in retailing. Historically, new forms of retailing have become established on the basis of competitiveness in price, achieved generally by a curtailment of retail services. Where resale price maintenance is effective and comprehensive, this way of entry is barred. The practice tends further to stabilize retailing in that it reduces the rate of growth of lower-cost firms by denying them the use of competitive price policies. It protects the less efficient, higher-cost firms.

The foregoing analysis helps to explain attitudes toward resale price maintenance. Historically, it generally owed its origins to the pressure of organized bodies of retailers (and wholesalers) anxious to avoid price competition, especially when threatened by new forms of retailing such as department stores and chain stores. Currently it enjoys its most vocal advocacy from such bodies of distributors. It also receives support from labor

unions of distributive workers. In some Western countries these supporters of resale price maintenance constitute a strong pressure group. On the other hand, it is rare for consumer groups to advocate resale price maintenance, although many of the claims made for the practice purport to show that it is in the consumer's interests.

**Effects on demand.** It may seem as if manufacturers of branded goods should oppose retail price maintenance, since its general effect in raising retail prices is against their interests. Nevertheless, many manufacturers seem to support the practice and use it where it is permitted and can be enforced. It must be that in some situations the adverse effect on sales of the higher retail price is (or is thought to be) more than offset by favorable consequences stemming (or thought to be stemming) from the practice. Several types of situations may be identified.

The most common situation—and historically the most important—is one in which the retailers favoring the control of retail price competition are able to influence materially the sales of particular brands (i.e., where together they can shift significantly the demand schedule of particular brands). In these conditions resale price maintenance secures the support of such retailers; the concomitant increase in their gross margins can be viewed as a toll the manufacturer has to pay for access to the established and effective network of retail outlets. But if the manufacturers of competing brands of a product all use price maintenance, the sales-promoting effects of the practice are neutralized; if each pays the toll, none has the advantage. Except in the special circumstances discussed below, the demand schedule for the product is unaffected; and therefore the higher retail prices are unfavorable to the manufacturers collectively.

The power of retailers favoring price maintenance depends on their relative strength (in terms of market share), their organization, their ability to influence consumer demand (through influencing the availability of the goods, their display, and point-of-sale advice or suggestions), and the absence of concerted action on the part of manufacturers to resist the retailers' pressure. In several countries the necessary combination of conditions was lacking in the grocery and clothing trades but present in the drug and liquor trades at the time when the price maintenance movement began. Again, resale price maintenance is relatively unimportant where innovating and price-competitive retailers have little difficulty in launching new brands or unbranded varieties of the goods they handle. Groceries and clothing may in this respect

be compared with books, automobiles, and cigarettes. The current long-term tendency toward impersonal methods of retail selling is likely to undermine resale price maintenance.

The influence of organized retailers is not the only reason why some manufacturers may find it profitable to have resale price maintenance. There are other ways, not dependent on dominant retailer support for price maintenance, in which the practice in certain circumstances may bring about favorable shifts of the demand schedule of a particular class of products, sufficient to outweigh the disadvantage of the increase in retail prices. While there is little difficulty in stating the conditions for an over-all favorable result for the manufacturers, it is not easy to discover whether these conditions are satisfied in any actual situation.

It is likely that consumer demand for some products is partly dependent on consumer access to the retail outlets that stock them and on information from retailers about them. Resale price maintenance stimulates sales insofar as assured bigger retail gross margins make possible and encourage more extensive and widespread stocking of the products and promote better-informed retail selling. It may seem, on the other hand, that in the appropriate circumstances—i.e., where the availability of the products and the provision of information are important in increasing demand—retailers have an incentive, even in the absence of resale price maintenance, to make the necessary investment in inventory and to incur expenditure on a knowledgeable sales force. But the incentive is weakened to the extent that consumers buy at lower prices from lower-cost shops after taking advantage of the facilities of higher-cost shops: retailers who provide the demand-creating services do not capture the full benefit of sales resulting from their outlays, which therefore tend to be reduced. (Incentive is also weakened to the extent—probably negligible in practice—that potential purchasers on impulse are deterred from buying by their knowledge that the price of the item in question is, or may be, lower elsewhere.) Resale price maintenance, by reducing the incentive for consumers to shop around for advantages, encourages the provision by retailers of the relevant before-sales services in the competitive search for customers. In such situations, the prevalence of which is debatable, manufacturers may wish to practice price maintenance. Resale price maintenance is, however, an indiscriminating method for encouraging retailers to follow desired inventory, display, and sales policies. In practice, it protects all retailers who are supplied with the prod-

ucts, irrespective of their trading policies, and stimulates the provision of services generally, not only presales services. Distribution through selected retailers is a more direct method for accomplishing the desired ends, and it can be achieved independently of resale price maintenance.

**Effects on manufacturer competition.** The conceivable advantages to be derived by the price-maintaining manufacturers in certain circumstances have so far been considered in terms of favorable shifts in the consumer demand schedule. Other possible advantages may arise where the consumer demand schedule is unaffected by the practice. Thus it is often implied that price competition in the retailing of their products would provoke more intensive competition among manufacturers and affect their selling prices to the trade and that, though their aggregate sales volume would be greater, profits would be smaller. This sort of effect is feared by many price-maintaining manufacturers, although it is difficult to determine whether these fears are justified in particular instances.

The transmission of price competition from retailing to manufacturing could follow one of two lines. First, retail price competition might lead to the concentration of more buying power in the hands of successful large retail enterprisers, who could use it to undermine stable trade-price structures. Second, price competition among retailers might cause variations in interbrand (retail) price relationships and hence in the relative sales of the various brands. Such changes in market shares might cause the disadvantaged manufacturing firms to reduce their trade prices in an attempt to regain lost business. These adjustments would inject instability into the structure of trade prices and might result in more intensive and persistent price competition. The second possibility may be restated in this way: resale price maintenance may be necessary or useful to underpin a manufacturers' horizontal price agreement or a noncollusive quasi agreement in tight oligopoly situations [see OLIGOPOLY]. The need for resale price maintenance is more apparent and more direct in those cases where manufacturers agree not to compete in price and reach the final consumers both directly and through independent distributors. The objectives of the agreement might not be fully achieved without the participation of the independent distributors, which could be secured or enforced by the imposition of resale prices. In this context, as in others, resale price maintenance is a partial substitute for vertical integration by manufacturers into distribution.

**Loss-leader selling.** No discussion of the economics of resale price maintenance is complete without some consideration of "loss-leader" selling. This ill-defined practice refers to selective deep price cutting by a retailer of a few well-known items, in order to attract customers to his store. Loss-leader selling is often and influentially claimed to furnish a good reason for the legalization of resale price maintenance. It is said that the price reductions involved are so limited in scope as to be of little benefit to consumers; that the practice is misleading in creating a possibly spurious impression of generally low prices; that it promotes monopoly in retailing; and that it causes meaningless fluctuations in the sales of brands selected as leader items, which disrupts their economical production. Since resale price maintenance removes the brands or products from the scope of loss-leader selling, it is said to protect both consumers and manufacturers. Precise evidence of the extent of undesirable loss-leader selling and of its alleged detrimental effects is, however, lacking or elusive. Resale price maintenance is in any event a crude method of stopping such selling: it precludes all forms of retail price competition, not only loss-leader selling, and the latter would presumably persist unless all products suitable for loss-leader tactics were price-maintained.

**Public policy.** Public policy toward resale price maintenance takes a variety of forms in different countries, as a few examples will show. It has been prohibited in Canada since 1951 as a restrictive practice against the public interest. The most common method of enforcing resale prices, the withholding of supplies from offending distributors, is prohibited (save in special circumstances specified in an amending statute of 1960). In the United States resale price maintenance is authorized in some but not all the states, and also in interstate commerce between "fair-trade" states. Differences in state laws and restrictive judicial interpretation of fair-trade laws have contributed to difficulties of enforcement and the collapse of the practice in the electrical goods and some other trades. In some states there is mandatory resale price maintenance in the liquor trade. The relatively favorable attitude toward resale price maintenance is regarded as anomalous by many observers in view of the per se illegality of horizontal price fixing, and the fact that resale price maintenance produces the main effects of horizontal price fixing in those retail trades in which it is comprehensive. In Sweden the practice has been prohibited since 1953, with provision for specific exemptions by a statutory body in cases where it is satisfied that such price main-

tenance reduces costs, benefits consumers, or otherwise promotes the public interest. The initial exemption of books is being terminated, and that of herrings has already been withdrawn.

In the United Kingdom enforcement of resale prices by manufacturers individually was facilitated by legislation until 1964, although a commonly used and powerful method of enforcement, the collective withholding of supplies by groups of manufacturers, had been prohibited in 1956. Legislation introduced in 1964 prohibits resale price maintenance, except for classes of goods specifically exempted by a special court. Exemption is granted only where the court is satisfied that the practice injures the interests of consumers or users less than it promotes them. As is the case in Canada, the legislation allows manufacturers individually to withhold supplies from dealers engaging in loss-leader selling of their goods.

Resale price maintenance is unimportant in underdeveloped countries, partly because enforcement is particularly difficult where there are several successive stages of distribution between supplier and final consumer, and also because the practice is inexpedient for manufacturers where their goods are resold in widely varying circumstances.

## RESEARCH AND DEVELOPMENT

### I. INDUSTRIAL RESEARCH AND DEVELOPMENT

Jacob Schmookler

### II. FINANCING SOCIAL RESEARCH

Henry W. Riecken

#### I

#### INDUSTRIAL RESEARCH AND DEVELOPMENT

While, as commonly used, "research" describes the quest for new scientific or engineering knowledge and "development" refers to the creation and the reduction to practice of new products or processes, "research and development" (R & D) is less than the sum of the two, for the phrase ordinarily denotes only research and development occurring in organizations established to perform them. The word order of the phrase may convey the impression that scientific or engineering discovery invariably precedes development, but development often leads to new discovery or occurs without it. Industrial R & D, to which this article is largely confined, is that portion of all R & D performed by or for business. It thus excludes R & D by nonindustrial institutions for themselves or for each other but includes R & D by such institutions for industry.

Research and development are not only ancient human activities but continue outside as well as inside R & D establishments. Although the importance of R & D has undoubtedly increased greatly, both absolutely and relatively, in recent decades, it is noteworthy that of 61 major inventions in the twentieth century, about half were made by independent inventors. As recently as 1953, less than half of all inventions patented in the United States came from corporate R & D establishments. The scientists, engineers, and supervisors in the operating divisions of industry contributed about half as many inventions to their employers' patent portfolios as did their R & D counterparts. The greater part of the reduction in production costs over time, even in the largest enterprises, typically results from hosts of minor, often unrecorded, changes in technique, introduced at the site by production

engineers and others, not from the larger innovations stemming from the enterprises' own R & D establishments. Hence, if based solely on statistics of R & D expenditures or employment, estimates of the volume of all resources allocated to advancing science and technology are too low, whereas, because of the greater relative growth of R & D, estimates so based of the rate of growth of all resources are too high.

Thus, the distinctive feature of R & D is not in the ends sought but in the formal organization of the means of attaining them, i.e., in the employment of professional scientists and engineers by lay bodies, private or public, for the specific purpose of advancing science and technology. In modern times the state—the princes and absolute monarchs of the seventeenth and eighteenth centuries—first provided the support for such employment, initially mainly as patrons of the New Learning; later, and increasingly, in the hope that discoveries and inventions of military, industrial or medical value would result. Not until the 1860s did business enterprise begin to consider that science had matured enough to make its systematic cultivation profitable at the level of the individual firm. For various reasons, chief of which, perhaps, was the superiority there of scientific and technological education, that development took place first in Germany, in the dyestuff industry, under the stimulus of the Englishman William H. Perkin's accidental discovery of synthetic mauve. The rise of industrial R & D under the auspices of individual business enterprises followed in other countries at varying intervals, in each case roughly determined by the extent of the lag in quality and character of the requisite education.

General Electric's laboratory, established in 1901, was the first in the United States and was followed by du Pont's in 1902; but not until World War I cut off the United States and the Allies from German pharmaceuticals and dyestuffs were their chemical industries able to develop appreciably in the fields pioneered by the German industry. The roughly one hundred private R & D establishments on hand in the United States at the start of the war tripled, with government aid, during its course. Most of the new ones survived in the postwar years, and by contributing to the stream of product and process innovations they helped drive more and more rivals to establish R & D programs of their own. The experience of World War II and the Korean War duplicated, on a larger scale, that of World War I, except that the number of American firms engaged in R & D has apparently not increased appreciably since 1953, growth since then

taking the form primarily of increased R & D per firm engaged.

The strong association of industrial R & D and defense explains why the aircraft and missiles industry alone accounted for one-third and the electrical and communications equipment industry for almost one-fourth of all R & D outlays in private firms in the United States in 1960. However, when only private R & D expenditures are considered for the same year, the chemical and allied products industry ranks first, with about one-fifth of the total, followed closely by electrical and communications equipment.

The pressure of defense requirements on industrial R & D is also reflected in the fact that the four American industries which received the largest amounts of federal funds for R & D in 1960—machinery, instruments, aircraft and missiles, and electrical and communications equipment—were the only industries that year to use at least 80 per cent of the R & D funds at their disposal for development alone. The expenditures in these industries on basic research in that year amounted to only 1 per cent of total R & D expenditures in aircraft and missiles, 3 per cent in electrical and communications equipment, and 2 per cent each in machinery and instruments. By contrast, basic research expenditures amounted to 18 per cent of total R & D expenditures in petroleum refining and extraction, 12 per cent in chemicals and allied products, 7 per cent in primary metals and food, and 4 per cent in industry as a whole. The small ratio of basic research to total R & D in the defense-linked industries is believed to result both from the characteristic complexity of the equipment produced and the arduous testing required and from the pressure for immediate results which usually attends publicly financed R & D expenditures in the United States, particularly in defense fields. However, other, more complex factors may also be involved.

**Interindustry variations.** The relative importance of R & D differs greatly among industries. In terms of company-financed R & D per employee among companies engaged in R & D, the leading industries in the United States in 1960 were chemicals and allied products, with outlays of \$980 per employee, followed by the instrument industry, with \$710, and the electrical and communications equipment industry, with \$600. The average for all companies performing R & D was \$390 per employee. At the bottom were textiles and apparel, with \$60, and lumber, wood products, and furniture, with \$90. Since industries differ greatly in the proportion of companies engaged in R & D

(and in the same direction as R & D outlays per employee), even these data considerably underestimate the true interindustry differences. Similarly, among the companies engaged in R & D in 1957 and having 2,500 or more employees, company outlays on R & D per dollar of capital expenditure varied from highs of \$2.83 in scientific and mechanical measuring instruments and \$1.30 in drugs and medicines to lows of 37 cents in industrial chemicals and five cents in primary metals, with an average of 41 cents for all industries surveyed.

While such differences presumably reflect corresponding interindustry differences in such factors as market opportunity, technological potential, durability of equipment, and comparative advantage of professional over nonprofessional research and development, the relative weight of these underlying determinants remains to be established. Indeed, while a profit-maximizing firm would, under conditions of certainty, allocate funds between physical plant and R & D so as to equalize the return to the marginal dollar spent on each, the actual relationships are unknown because data needed for calculating the returns to R & D under typical circumstances are nonexistent. Similarly, efforts "to explain interindustry or interfirm differences in growth rates in terms of correlated differences in R & D rates have not been wholly successful thus far, because the lines of causality run in both directions.

**Organizational considerations.** As implied above, in Western nations generally, private firms now do most of the R & D, whether for their own account or the government's. This tendency is most pronounced in the United States, where in 1962/1963, for example, of an estimated national total of \$16,400 million spent on all R & D, 70 per cent was spent in, and 30 per cent was spent by, business firms—compared with 16 per cent spent in, and 67 per cent by, the federal government. Of the R & D expenditures of business enterprise, only 3 per cent was for work done in nonprofit institutions, and most of that was on behalf of the individual spending enterprise. By contrast, in the Commonwealth countries and western Europe relatively more government R & D is done "in house," and relatively more R & D for industry is performed in industry-operated research centers, financed by industry alone or jointly with government. Its traditionally more confined role has caused the government of the United States to eschew a major direct part in advancing the technical arts, outside of the military and health fields, and such new and expensive fields as nuclear

power and space, which are felt to be politically or militarily important, or such old, economically distressed and politically powerful fields as agriculture and coal mining. The minuscule amount of cooperative research in American industry is explained in part by the fact that the patent laws create monopolies that would be illegal under the antitrust laws if created by other means.

Debate on the relative merits of alternative ways of organizing industrial R & D, as well as on such related matters as the efficacy of existing patent laws—and particularly whether the government or the private contractor should hold title to patents on government-financed business-produced inventions—has swelled with the increase in R & D expenditures and with the growing recognition of the importance of technological progress to economic growth.

Thus, some argue that a shift in the site of industrial R & D from the individual firm to an industry center might eliminate wasteful duplication, permit economies of scale in R & D and the pursuit of projects too expensive for a single enterprise, and in principle make immediately available to all what would otherwise be patented or kept secret. There is, however, some danger that under such an arrangement unusual but occasionally great projects would be neglected; that individual firms would not risk innovating, when rivals could freely imitate after most of the risks had been eliminated by the pioneering firm; and that being removed from the point of application and lacking competitive pressure, R & D would be inefficiently conducted. Only about 15 per cent of the inventions patented by the U.S. Department of Agriculture and the Tennessee Valley Authority are used by private industry (although they were developed for that purpose), while between 50 and 60 per cent of inventions patented by private firms are used commercially. Since the R & D programs of the two agencies resemble those of industry centers, these differences in utilization rates have obvious pertinence to the question.

Undoubtedly the growth of elaborate, technologically complex, and extremely expensive systems has increased the optimal size of some R & D projects, as in the armaments, space, power, and communications fields. Hence, some individual R & D projects cost billions. This fact, also, has seemed to justify greater centralization of industrial R & D to insure efficient articulation of interdependent elements of industrial technique and apparatus. However, the weight of present evidence suggests that decision making in large R & D projects may already be too centralized in the United

States when radical advances are sought, because the discoveries and inventions on which such advances must be based cannot be forecast with the precision needed to preplan their interrelations.

**Scale considerations.** On another plane, some have urged relaxing the antitrust laws because of presumptive economies of scale in R & D. Large firms, it is argued on theoretical grounds, can afford R & D projects that small ones cannot. Large firms, having a longer time-horizon, can wait longer for returns; having better access to capital, they can more readily implement R & D findings; being more diversified, they are more likely to find useful the unexpected results of R & D; and having a more protected market position, they are able to capture more of the gains from new knowledge and so have a greater incentive to finance any given R & D project. These factors, it is argued, explain why, among American manufacturing firms in 1953, for example, only 10 per cent of those with 8 to 499 employees had or financed R & D programs, compared with 42 per cent for firms with 500 to 999 employees, 60 per cent for firms with 1,000 to 4,999 employees, and 94 per cent for firms with 5,000 or more employees; and they also help explain why in 1960 company-financed R & D for American manufacturing firms engaged in R & D amounted to 2 per cent of sales for firms with 5,000 or more employees, compared with 1.4 per cent for firms with 1,000 to 4,999 employees. The greater progressiveness of large firms, which such data and theoretical reasoning appear to imply, it is maintained, cannot be fully exploited if the individual firm is prohibited by law from achieving dominance in its market.

However, small firms appear to have certain offsetting advantages in the domain of R & D. Because the small firm has shorter lines of communication, its R & D scientists and engineers are likely to know the firm's production problems and the product requirements of its customers more precisely than are similar personnel in a large firm. Perhaps this is one reason why small firms use commercially about three-fourths of the inventions they patent, whereas big firms use only half. The greater contact of the scientists and engineers of the small firm with the problems the firm confronts may result in less lost motion in the R & D process itself, for firms with under 5,000 employees spend half as much on R & D per patented invention as do larger firms. Moreover, research and development on the part of operating scientists, engineers, and supervisors probably occurs more often in small than in large firms, since the division of labor in the latter is characteristically

narrower and more formal. Hence, variations in R & D per dollar of sales between firms of different sizes are a misleading index of the corresponding variations in the amount of new knowledge produced within the firms. Finally, the relative frequency of projects so large that only a giant enterprise can mount them does not seem high, for after a certain, not very large size, further increases in the size of the firm are not associated with any increase in R & D as a percentage of sales or with an increase in the proportion of firms engaged in R & D.

The ambiguity of existing evidence suggests that the net effect of different patterns of industrial organization and of the organization of industrial R & D upon the discovery and use of new knowledge may be small, perhaps because a strikingly favorable effect of a given pattern in one direction tends to be more or less offset by adverse effects in other directions. In general, it seems probable that an acceptable analysis of the problem must await a firmer understanding of the processes by which new knowledge is created and disseminated.

#### II

#### FINANCING SOCIAL RESEARCH

As the social sciences have evolved from their origin in moral and political philosophy to their present state as empirically grounded observational and experimental sciences, they have not only lost some of their speculative tone but have added the costs associated with the systematic collection of data. In this respect they share some

of the financial problems of the physical and biological sciences, even though the social sciences generally do not use such extensive (and expensive) equipment. Instead, the costs of research in the social sciences consist principally of payment for the skilled (and often professional) labor of interviewers, observers, experimenters, coders, data analysts, and those who construct questionnaires and develop tests of various kinds. In recent years outlays for high-speed electronic computers and the professional and technical labor associated with their use have increased rapidly—a trend that seems likely to continue to grow as it becomes possible (and desirable) to work with larger and larger bodies of data. The travel and other expenses associated with cross-cultural or multinational research are another factor in rising costs.

For these reasons, modern social research is too costly to be borne by the individual investigator, and yet, with the exception of some kinds of applied research, it does not produce results that have sufficient private commercial value to encourage business ventures. Hence, like the physical and biological sciences, the social sciences depend upon grants and gifts from private and public sources or on contracts for research services, usually with governmental agencies. The nature of the source of support and the similarity or difference in interests and motives on the part of the grantor and the researcher make for some interesting and difficult problems. These include the possibility of conflict between the "fundamental research" interests of the social researcher and the need which the supporting organization has for "practical" results; the possibility that the sponsor will directly or indirectly try to influence the outcome of the research or the conclusions drawn from it; and the possibility that the sponsor's interests may make it risky or impossible even to inquire into certain topics. Less sinister but just as important is the fact that the grantor's interests are likely to be directed toward immediate and very contemporaneous social problems, so that a researcher with a particular topical interest may be overwhelmed with funds for a while and, later, when interest has shifted to another question, find himself without a patron in sight. Finally, there seem to be some problems that are chronically low on a society's priority list (such as the psychology of aesthetic experience) and others that usually have a high place (the analysis of economic fluctuations, for example). None of these problems is specific to the social sciences, for an instance of each can be found in one or more of

the physical and biological sciences. Some are, perhaps, exacerbated by the close connection between social research and human welfare, economic interests, political power, and ethical, moral, and judicial issues. Since the patterns of support in the United States are highly varied, and since they are *relatively* well documented, discussion in this article will be confined to the United States.

**The role of universities.** In the United States scientific research of all kinds has traditionally been carried on largely in and through universities and operating government bureaus, rather than through independent institutes or academies of science. Furthermore, until recently at least, the largest amount of scientific research was carried on in the universities, although an increasing share of the cost of research has been borne by the government.

Accordingly, among *performers* of research the most important institution is the college or university. Private universities in the United States are supported chiefly through endowments, fees from students, and rents or royalties, supplemented by gifts (from nongovernment donors) and by grants or contracts for research or services performed. Public universities obtain their funds chiefly from the legislative bodies of the individual states or cities in which they are located, although they may also have small endowments, rents, royalties, and the like, and they usually receive substantial amounts of grant or contract funds for research and services. In both private and public universities, funds for grants or contracts for social science research may come from the federal government, from industrial corporations, from private foundations, labor unions, and other nonprofit organizations, and from private individuals.

There is considerable variety in the specific arrangements for performing research in universities. Often an individual member of a faculty will, with the help of a graduate-student assistant and a clerical worker, carry out the major share of the collection and analysis of data and the preparation of a technical article on a topic in which he has a special personal interest and which he himself has chosen and defined. At the other extreme is the large, teamwork project, in which several senior investigators and many juniors, assistants, and clerks take part. Often such projects are initiated and contracted by organizations outside the university, and the interest of the faculty member is likely to be tangential, partial, or secondary. Between these extremes one can find a wide variety of intermediate arrangements.

We can distinguish, then, two dimensions: the

size of the research project (in money, time, and personnel) and the extent to which the problem originates spontaneously from the scholarly or professional interests of the senior investigator(s). These two dimensions are not precisely parallel, but they are far from orthogonal.

To a considerable extent the sources of funds are correlated with these two dimensions of research. The lone researcher with a single assistant is more often supported through the university's own research funds, when such are available; the large team working on some problem presented by an outside agency is likely to be supported through a contract with a firm or a government agency. The chief reasons for this situation are historically rooted in both the development of methods of research in social science and the emergence (especially after 1945) of new forms of support. Beginning in the classical tradition of individual scholarship, which placed reliance on documentary evidence and direct but somewhat unsystematic observation, social science research in the universities was originally the act of individuals, working slowly, independently, and on a fairly small scale. Gradually, the introduction of new techniques, especially sample surveys and experiments, together with machine processing of data and statistical techniques, enlarged the scholar's need for assistance. The private foundation's grant or fellowship for travel, study, and field work served the individual scholar well during the period when methods were developing, but the costliness of the new techniques taxed these resources and virtually overwhelmed the universities' own resources. Social science research was severely limited, chiefly by lack of funds, through the 1940s and 1950s. There are still financially imposed limits, and the social sciences do not yet enjoy the extent of support in the United States that the physical and biological sciences do. After World War II, however, the development of government financing for social science research greatly changed the situation and permitted social scientists to take on larger projects and more extensive and complex studies than had previously been possible for any except a few.

The increased interest of government bureaus in social science research is probably attributable to three things: the demonstration, during the war, of the practical contribution of social science research to selection, training, and other manpower problems; the growth of agencies in the government (from 1935 on) that were concerned with administering social and economic legislation, with the lagging realization that such administrative efforts could not succeed without research on the

problems that the agency had to handle; and the developing awareness that basic research on society and human behavior should be supported both for its own sake and in order to develop the basis for future applied work. Since the pattern of supporting research through university facilities had already been laid down in the natural sciences; since the trained personnel were available in universities (and it could be argued that sponsored research there provided opportunities for training graduate students); and finally, since there was no existing tradition or machinery for the establishment of independent research institutes or academies, the pattern of federal support through the universities grew up.

The detailed arrangements for financing government-supported projects (which form a substantial portion of all sponsored research) at universities can be exceedingly complicated, and this article will attempt to outline only the major aspects of the most common cases. As a rule, the senior investigator on a project is a regular member of the university faculty, and normally part of his salary is paid out of the university's own funds. The junior professional members of the project group are usually paid exclusively out of the grant funds, as are the clerical and other assistants. Although this pattern is in flux, it is generally true that research staffs have enlarged more rapidly than regular faculty positions, with the result that there are sometimes, in effect, two groups of equally competent social scientists at a university: one, the regular faculty, tied to the university through teaching and through tenure appointments; the other attached more uncertainly, through the research grant, with few or no teaching opportunities and with an appointment whose duration depends solely on the duration of the grant. Indeed, this development of two groups whose link with the university is different has produced many stresses and is one of the more serious problems arising from short-term financing of large-scale research.

Agencies of the federal government, operating on annual appropriations from the Congress, have tended to make short-term commitments to university researchers. Some agencies fund research on an annual basis, while others commit funds from the annual appropriations to support selected projects for as much as seven years in the future. Research funded on an annual basis suffers from uncertainty, the need to solicit additional funds at frequent intervals, and the difficulty of providing stable support for the members of the project staff.

On the other hand, the presence of outside research funds has often enabled the university to

enlarge and enrich the opportunities for instruction and practical training of graduate students, as well as to provide technical consultation and assistance to the regular faculty.

One further aspect of the financial arrangements between the universities and the sponsors of research remains to be commented upon, namely, the support of indirect costs which accompany the establishment of research projects. As long as social science research was the work of individual scholars who used only the space, light, heat, books, journals, and other facilities that the university was accustomed to provide for its staff, there seems to have been no question raised about "overhead" costs. But with the beginning of federal government *contracts* for research, which often involved expanding space, facilities, staff, and ancillary services, the situation changed. Universities began to notice that sponsored research, while offering increased research opportunities for their faculties and students, also resulted in increases in operating costs for the university. Accordingly, a system of payment for *indirect costs* was established and has been perpetuated. Private foundation grants do not always include an overhead cost for the university, while federal government grants and contracts always do. This situation arises partly out of the fact that research in the United States has not, on the whole, been conducted through separately established institutes, where the capital costs of research facilities would be reflected in direct outlays for buildings, equipment, supporting services, and maintenance.

**The role of the federal government.** In terms of funds spent, the federal government plays a distinctly secondary role in the *performance* of social science research. While the several departments of government maintain laboratories and other research units, the research efforts in these units are smaller in size than those of their counterparts in the universities. Establishments such as the Socio-Environmental Laboratory and the Adult Psychiatry Branch of the National Institute of Mental Health, the Wright Air Development Center of the Air Force, the research sections of the Bureau of the Census, the Personnel Research Branch of the Army, and the Agricultural Research Service and Agricultural Marketing Service of the Department of Agriculture are all budgeted in the departmental appropriation made annually by the Congress, are staffed by civil servants, and in general direct their research toward the practical problems which they encounter in performing their assigned missions. A unique case is the Smithsonian Institution, which is both public

and private. Established by private initiative and receiving support, in part, from private funds, it nevertheless has a charter from the Congress and enjoys some measure of federal government subsidy, which is appropriated annually. The Smithsonian's chief contributions to social science have been in anthropology and archeology.

Most of the research *performers* within the federal government devote themselves to applied social science rather than to basic research, which receives much less support. This situation arises, no doubt, from the fundamentally practical or administrative orientation of most government bureaus and reflects insufficient recognition of the present state of social science, where a great deal of basic work must be done before the development of practical applications from a scientific base is possible. Basic research usually demands smaller amounts of money than applied work does but requires consistent funding over relatively long periods of time, during which no "useful" results may emerge. It is difficult to resist the demand for "practical" information which administrators and legislators can use. One of the habitual and trying cycles in social science is that which begins with administrative optimism; is followed by an increase in support, together with an increase in demand for immediate results; and then fades into a period of administrative disillusionment, terminated by the cutting off of funds. Instability of support hampers immediate accomplishment and discourages research workers from undertaking substantial, long-range projects that might yield greater results. These considerations, it should be mentioned, have pertinence to government, as both a performer and a source of research funds, but have also afflicted other sectors, such as private foundations, on occasion.

**The role of other performers.** Universities and federal government research units account for nearly four-fifths of the funds spent for social science research in the United States. Of the remaining one-fifth, only a small amount is spent by the private foundations, which play a very minor role as *performers*; there are very few social scientists who are active in research on foundation staffs. The Russell Sage Foundation is an exceptional case, and its operations are perhaps typical of the few performers in this area: a small staff in social psychology devotes some share of its time to the pursuit of research that its members organize and that is related both to the scientific interests of the staff and to the objectives of the foundation.

A larger share of funds is disposed of by a variety of nonprofit research institutions such as

the Stanford Research Institute (SRI), the National Opinion Research Center at the University of Chicago (NORC), the RAND Corporation, the Systems Development Corporation, the Bureau of Social Science Research, the National Bureau of Economic Research, the Institute for Social Research at the University of Michigan, and the Bureau of Applied Social Research at Columbia University (BASR). These nonprofit, nongovernmental enterprises are a postwar phenomenon in the United States. Some have university connections, but as a rule they are without endowment and without students and tuition fees. These institutions have developed and flourished simply by engaging to conduct both basic and applied research on questions that are important to somebody, usually somebody outside the staff of the institute or center. They have received support from, and conducted research for, industrial corporations, labor unions, agencies of the federal government, private foundations, individuals, and colleges and universities. The pattern of financial arrangements, if it can be called a pattern, is extremely variable, ranging from the "one-client" organizations, such as the Operations Research Office, which depends almost entirely upon federal government funds, to the more variegated institutions (NORC, SRI, BASR), which accept commissions from all of the categories of "clients" enumerated above. The chief financial-administrative problem of such units is to maintain continuity of professional personnel and the scientific integrity of their work, in the absence of any continuous support from a source whose interest in social science research is not restricted to a single problem. In other words, the task of the director of such an institute or corporation is to provide continuing funds for the operation of the whole enterprise: he must not drive his research staff to distraction by frequent and arbitrary shifts in their assignments, yet he must avoid periods of low income during which valuable staff members must be let go because their salaries cannot be paid. The glory of a director of a private nonprofit institution stems from his skill in maintaining a substantial *scientific* productivity by the agency while at the same time providing the "client" with useful answers to his (not always scientific) questions.

There are a smaller number of independent organizations which operate on a profit basis. Except for this financial difference, they share many of the characteristics and problems of the independent nonprofit institution, although they do not have even a tenuous university affiliation. Such organizations are common in the physical sciences, where the pattern was established, and there are a grow-

ing number in psychology, which receive funds from both government and industry sources.

*Social Science Research Council.* The Social Science Research Council is not itself a performer of research but acts as a source of stimulation for needed research, better training for research, and support for research. A private organization of social scientists, it has developed close relations both with private foundations and with government agencies that share its interests. The governing board of the council consists of social scientists, as does its professional staff. Its committees, which are of two kinds, are composed of social scientists, largely university faculty members who serve without remuneration. Some of these committees administer programs of research-training fellowships and grants for research; others survey the status of research in selected fields, develop plans for needed research, organize conferences, and supervise a variety of programs, for which the council receives grants from private and public sources. Its continuity is assured by the fact that it has a basic endowment from private sources, although the bulk of the work accomplished by council committees and grantees is funded by short-term grants received from various sources. The governance of the council is effectively in the hands of professional social scientists.

*Sources of funds.* The matter of where the funds for social science research come from can be dealt with more briefly than can the financial complexities of performers' activities. There are two major sources of support: the federal government (chiefly the Department of Health, Education, and Welfare, the Department of Defense, the Department of Agriculture, and the National Science Foundation) and private foundations (chiefly Carnegie, Ford, Rockefeller, and Russell Sage). The principal flow of funds is from these two sources to the universities, with considerably smaller amounts going to nonprofit institutions. Private industry also supplies funds for social science research, although data on expenditures are not easy to obtain. Private industry is probably more important as a source of funds than as a performer of research, although it is difficult to estimate the amounts spent by industrial performers because of the problem of deciding which activities should be called social science research (as distinguished from routine data collection for the purpose of making, say, a marketing decision).

*Further problems.* Besides the problems already mentioned—the growth of "secondary" research staffs at universities and the lack of continuity and stability in independent research organizations—the foregoing description of the institu-

tional arrangements for financing social science research may have raised other questions, especially in the minds of those who are not entirely familiar with the operations of the system. For example, it is obvious that the federal government, as a principal source of revenue, could exert a large, perhaps an undue, influence on social science research. Under such conditions, are social scientists able to work on important problems or are they frequently distracted and diverted either to trivial questions or away from significant but controversial ones?

It is important to realize that although university-based social scientists are heavily dependent upon government sources for support of their research, it is equally true that government agencies are heavily dependent upon university-based social scientists for advice and for the professional and technical skills needed to carry out the research which government agencies want. Virtually every government agency that makes grants or contracts for social research uses advisory committees made up of faculty members of university social science departments. Many of the staff members in agencies making grants and contracts are themselves former university professors, whose understanding of the needs, requirements, and values of the social science community is therefore fairly good. To a considerable extent, then, policies governing federal government support of social science research are shaped by the values, and indeed the interests, of those who are most affected by these policies. It is true, of course, that the particular mission of the government agency will affect the sort of social science research it supports and encourages. Some agencies, however, devote all or a substantial part of their funds to the support of basic research in the social sciences, and they presumably are governed almost entirely in their project-granting decisions by the interests and capabilities of available social scientists who apply to them for assistance. At the opposite extreme, there are a very small number of research projects that are virtually ordered by agency representatives, who conceive them, initiate the negotiations for their accomplishment, and specify how they are to be done. Such highly specific task requests play a relatively small role in shaping the given field of inquiry, both because there are comparatively few such commissions and because most university and independent research agencies feel cramped by such specific requests and avoid accepting them whenever possible. Extreme financial need is usually the reason given by the research director of an independent institute which accepts such a commission from a federal agency or, for that matter, from industry

or business. Somewhat more influence derives from the extensive support that federal agencies have provided to certain fields: for example, agricultural economics and clinical psychology. Both these fields have been the objects of truly massive support for a number of years—agricultural economics since the 1920s and clinical psychology since the 1940s. The availability of funds in these two fields has undoubtedly influenced the career choices of graduate students who had no clear commitment to a particular subfield. Perhaps the strongest influence wielded by federal government agencies has been a negative one—that is, the government has exerted influence either by deciding not to support a field or by simply failing to take responsibility for the nurturance of a particular field. In this respect, both history and political science have probably experienced greater neglect from federal government agencies than any other of the social sciences. Psychology has been relatively well supported; anthropology and sociology somewhat less well. Perhaps because of a conservatism inherent in the situation, newly developed fields of inquiry, such as the administrative sciences, have often had great difficulty becoming established and securing support through federal agencies. To some extent the same point can be made with regard to particular topics or problems within a given discipline—topics that have been undersupported or wholly ignored. Until relatively recently at least, research on the social and behavioral aspects of birth control has been regarded as taboo or at least very touchy and dangerous for a federal agency. Similarly, inquiry into problems associated with racial segregation or the social changes associated with integration has had relatively little support from federal agencies. It seems probable that research on contemporary national politics has a dim future among federal agencies. This last example illustrates the point that it is not merely bureaucratic prudence that keeps agencies from encouraging research on certain controversial topics. Rather, it is quite evident that it would be difficult to achieve detachment and objectivity in judging research proposals when the research directly or indirectly affected the institution proffering the support. For that reason it may be more appropriate for private foundations to undertake the support of research on national politics, federal government operations, the evaluation of foreign policy, and other questions on which individual federal agencies are not likely to be able to maintain objectivity and detachment.

The implication should not be drawn from the preceding paragraph that government agencies are inherently more conservative in the social science

research which they finance than are private foundations. In terms of intellectual and scientific innovation, both federal agencies and private foundations have been sometimes conservative and sometimes innovative. The chief difference arises, however, in the duration of support for a "new idea." It is characteristic of private foundation funding that after having given initial impetus to some plan, the foundation will withdraw its support and turn its attention to other ventures, whereas the federal agency is typically more likely to continue extended and dependable support of a given venture for which it has taken initial responsibility. For this reason, there may be in federal operations a certain degree of inflexibility, which grows as the number and variety of programs to which the agency is committed increases. As it is difficult to bring any given activity to an end, it becomes increasingly difficult to undertake new activities unless there is a constant increase in the funding ability of the agency. This disease, however, does afflict some private agencies and should not be thought of as something unique to the public sector. Of course, although it means that government-supported social science research is somewhat less flexible in its terms of preference, it may also mean that it is more dependable and continuous.

Finally, it should be clear that the growing support for social science research at universities has had certain consequences for the style of life and pattern of organization at these institutions. Increased support has made it possible to undertake larger-scale projects, often in remote and inaccessible parts of the world, and often concerned with a much larger volume of data than social scientists of fifty years ago would have believed possible to handle. This growth in size and in sophistication has provided better opportunities for training future social scientists during their graduate school years, and it has produced new roles of an administrative, managerial, and entrepreneurial sort for faculty members. Although the day of the lone scholar working in a library or with direct personal observations has far from vanished, nevertheless, the spread of larger research teams has demanded an increase in scholars with managerial abilities. The head of a large research team must be skilled at defining the problem to be studied, at recruiting and employing personnel, and at managing the logistics of the operation. Above all, under the project system of grant and contract making, he must have the entrepreneurial skill necessary to secure, often from more than one source, the required support and to maintain the

flow of funds, so that the continuity of the team effort will be upheld.

Furthermore, the existence of team efforts of this sort has increased the pressure on university administrations to establish institutes, interdepartmental committees, and other interstitial organizational units within the traditional academic structure. Such a demand for new organizations does not reflect, of course, simply the presence of additional funding but rather indicates the existence of new strains, new lines of interest, and new intellectual developments which may seem to justify novel organizational arrangements. The role of outside funds in this kind of development is simply to make possible what might have been difficult or impossible within a traditional departmental structure. To repeat, such institutional innovations are not new (the Institute of Human Relations at Yale University was established in the 1920s), but the trend has been accelerated by increased funding in recent years.

## RESPONSE SETS

It is usually presumed that the score a person obtains on a psychological test is determined by the content of the items and that this score reflects such characteristics as the examinee's knowledge on achievement tests, his abilities on aptitude tests, his interests on interest inventories, his traits on

personality measures, and his opinions on attitude scales. Evidence in support of this presumption is important in establishing the meaning of the score. The responses a person makes to a test, however, are a function not only of item content but also of the form of item used and of other aspects of the test situation. The item form or the test directions, for example, may induce temporary preferences that systematically influence responses, such as the tendency to respond quickly rather than accurately. In addition, the examinee may characteristically bring to tests of certain formats various test-taking attitudes and habits, such as the tendency to agree, that produce a cumulative effect on his score. Properties of test form, then, may differentially influence an individual's mode of item response and may also permit the operation of preferred or habitual styles of response. These stylistic response consistencies are called response sets. A response set is a habit or temporary disposition that causes a person to respond to test items differently than he would if the same content were presented in a different form (Cronbach 1946, p. 476; 1949).

A test presumed to measure one characteristic may thus also be measuring another characteristic (response set) that might not have been reflected in the score if some other form of the test had been administered. In this discussion the term "form" is used loosely to include all aspects of the test situation to which the examinee may react, including the form of the item, the tone of its statement, the number and nature of response alternatives provided, the test directions, instructions for guessing, and the presumed use to which the scores will be put.

Response set variance is of two major types: (1) transitory consistencies limited to a particular test or to a single testing session and (2) reliable, stable consistencies with some generality over tests and situations. Two forms of stable consistencies may also be distinguished in turn: (a) the type that reflects durable but relatively trivial individual differences (perhaps in language usage or expressive habits) and (b) the type that reflects significant aspects of personality (Cronbach 1949). To emphasize this latter type of stable response-set variance and its potential usefulness in the measurement of personality characteristics, Jackson and Messick (1958) suggested that it be renamed "response style." A response style, then, is a consistency in the manner of response to some aspect of test form other than *specific* item content; it is relatively enduring over time and displays some generality in responses both in other

tests and in nontest behavior (Jackson & Messick 1962, p. 134).

**Kinds of response sets.** The operation of response sets of various kinds has been detected on tests of several forms in widely different content areas, including ability and achievement tests, personality questionnaires and checklists, interest inventories, performance ratings, and attitude scales. The following are some of the major kinds of response sets investigated thus far.

**Tendency to gamble or guess.** Reliable individual differences have been noted in the tendency to guess when in doubt (see Cronbach 1946). These gambling consistencies vary over a wide range, from responding only when certain to attempting every item. Because he usually has partial knowledge, the frequent guesser tends to receive higher scores on ability tests than the more cautious respondent; and this difference in scores is not entirely eliminated by corrections for chance or random responding. Although one might attempt to assess partial knowledge and take it into account (Coombs, Milholland, & Womer 1956), a simpler approach to the reduction of gambling's extraneous influence on scores would be to use (or claim to use) scoring formulas that penalize guessing. However, even though the threat of severe penalties may reduce the incidence of guessing on the average, bold students will still tend to guess more than cautious ones, and differences in gambling propensities will still influence individual scores. Because of this, Cronbach (1950) has recommended that examinees be directed to answer every item, except on those occasions when the response set is intended to measure some personality characteristic, such as cautiousness and risk taking (Swineford 1938; Messick & Hills 1960; Kogan & Wallach 1964).

**Speed vs. accuracy.** When speed is an important aspect of test performance, as when the time limit is insufficient for the completion of the test, individuals tend to differ reliably in their preferences for responding rapidly as opposed to carefully and accurately (Cronbach 1950). This set to work rapidly may be related to the gambling tendency, whereas the opposing preference for carefulness appears to represent a more cautious test-taking strategy.

**Evasiveness, indecision, and indifference.** Substantial reliability has been repeatedly demonstrated for the tendency to use the noncommittal middle category on several response options, such as the neutral category on attitude scales, the "?" on the "yes?-no" format, the "indifferent" choice on the "like-indifferent-dislike" option, or the

"uncertain" response on "agree-uncertain-disagree" (Broen & Wirt 1958; Cronbach 1946; Lorge 1937). Possible bases for these preferences seem manifold. They may stem from a motivation to evade revealing a definite position. They may reflect indecision in the face of difficult choices or indifference in the face of uninteresting ones. As a cautious unwillingness to commit oneself, they might be inversely related to the gambling tendency discussed above. Or they may reflect consistent differences in the interpretation of category labels.

*Interpretation of judgment categories.* Reliable preferences for particular response options have been observed that appear to be partly due to stable differences in viewpoint about the meaning and scope of the judgment categories provided (Cronbach 1946; 1950). Thus, for example, two persons with the same pattern of interests would obtain quite different scores if one consistently interpreted the "like" category in a "like-indifferent-dislike" format to include anything that he did not dislike while the other limited its application to those things that he actively desired.

*Extremeness.* Another example of preferences for particular response options is the tendency to mark extreme categories as opposed to more moderate ones on rating scales and Likert-type formats (which permit degrees of agreement and disagreement). Individual differences in the use of extremes on rating scales are very reliable and, for attitude scales at least, appear to be relatively independent of item content (Kogan & Wallach 1964; Peabody 1962). In addition to its possible occurrence as a result of differences in the interpretation of judgment categories, the tendency to respond extremely may also stem from a "desire for certainty" or may reflect self-confidence in expressing opinions (Brim & Hoff 1957; Kogan & Wallach 1964).

*Confidence.* The tendency to select the option "correct answer not given" in multiple-choice ability tests has been suggested as a response-set measure of self-confidence (Mullins 1963). The tendency to choose this alternative on a verbal test was found to be significantly correlated with the same tendency on a spatial test, even with ability held constant.

*Inclusiveness.* When no specific limit is placed on the number of responses required (as in instructions to "list the activities that interest you" or "mark those statements that reflect your attitudes"), some individuals consistently tend to give many responses while others tend to give few (Broen & Wirt 1958; Cronbach 1946; 1950). The

tendency to be broadly inclusive in responding may be a reflection of individual differences in the perceived breadth of categories used in classification (Pettigrew 1958), or it may reflect uncriticalness in delimiting these categories and in establishing criteria for inclusion.

*Criticalness.* Consistent differences in the strictness of evaluating the equivalence of objects or their acceptability in terms of some standard have been interpreted as a response set of criticalness. Scores for this disposition (for example, the tendency to respond "different" in appraising the equivalence of two possibly alternative expressions or to respond "ambiguous" in judging the acceptability of a sentence as an unambiguous statement) were found to be reliable, significantly intercorrelated, and generally unrelated to content measures from the same tasks (Frederiksen & Messick 1959).

*Acquiescence.* The tendency to answer "true" on true-false examinations and tendencies to respond "agree," "like," and "true" on personality, interest, and attitude questionnaires have been found to be reliable and stable over time (Cronbach 1942; 1946; 1950; Couch & Keniston 1960; Jackson & Messick 1958). This acquiescence tendency operates primarily when the respondent lacks knowledge or certainty about his answers. On achievement tests, then, acquiescence would be expected to reduce the spread between knowledgeable and poor students on true items and to increase it on false items, thereby lowering the reliability and validity of the "trues" score and raising that of the "falses" (Cronbach 1942). On personality and attitude scales, acquiescence would tend to occur when items are ambiguous, vague, or so neutral that their desirability or undesirability is unclear (Jackson & Messick 1962). Individuals acquiescing to personality questionnaires were shown in one study to possess personality characteristics of extroversion, expressiveness, and impulsivity (Couch & Keniston 1960), thus suggesting that such acquiescence has some basis in stylistic consistencies of temperament.

There are several indications that the tendency to agree with extreme and sweeping generalizations is a different, although correlated, response style that has been called the tendency to "over-generalize" (Jackson & Messick 1958). Measures of this tendency have been found to have significant negative correlations with both criticalness and verbal ability (Frederiksen & Messick 1959), as well as with the abilities to overcome embeddedness and distraction (Forehand 1962). This suggests that the tendency to overgeneralize is more

a function of cognitive and intellectual limitations than it is of temperamental dispositions.

*Tendency to respond desirably.* The tendency to respond not to specific item content but to a more general connotation of an item's meaning—namely, its desirability—has been found to be highly reliable (Edwards 1957). Although this tendency to respond in a socially desirable way is thus not completely independent of item content, it nevertheless represents a general response consistency that is different from the more limited consistencies generated by the truthful endorsement of specific item content. It qualifies as a response set under the definition given above (Cronbach 1946), since its operation causes individuals to give different responses when the same content is presented in different forms. Thus, responses to statements in a true-false form might be determined largely by the desirability of the characteristics described; but when the same items are presented in a forced-choice form, with alternatives matched for judged desirability, the responses are more likely to be determined by specific content (Edwards 1957).

On the basis of an obtained high relation between desirability responding and content scores (Edwards 1957; Jackson & Messick 1962), a major portion of response variance on several personality questionnaires has been attributed to the set to respond desirably. The meaning of this relation, however, remains controversial. Some theorists feel that desirability responding represents an attempt to put oneself in a favorable light, while others feel that it results from an accurate description of the individual's actual desirability. It is unlikely that respondents would deliberately fabricate on such a large proportion of their responses, particularly under research conditions; but it also seems unlikely that accurate self-descriptions would produce a single pervasive dimension intimately associated with desirability that on many questionnaires overshadows the various content dimensions of personality. An alternative hypothesis interprets desirability responding not in terms of deliberate misrepresentation but chiefly in terms of an autistic bias in self-regard (Damarin & Messick 1964).

*Tendency to fake.* The tendency to fake and distort responses in an attempt to bias the impression given to the examiner represents another reliable type of desirability responding. This tendency, which must be at least partially deliberate, is usually assessed on items with a wide discrepancy between the judged desirability of the characteristic described and its frequency of occurrence.

Thus, a penchant to claim desirable but extremely rare characteristics, or to deny undesirable but extremely common frailties, would be interpreted as lying. Such items appear in several "lie" and malingering scales, which have been found to intercorrelate in factor-analytic studies to form a dimension of response that is distinct from the type of desirability responding described above (Edwards & Walsh 1964; Jackson & Messick 1962). The operation of this bias in self-report may be appraised through the use of these lie scales so that particularly suspect respondents may be detected.

*Tendency to deviate.* Consistencies have been noted in the tendency to deviate from a modal response or from the typical response of some criterion group. Since pathological groups, which are deviant from normals in critical ways, also display deviant response styles on certain tests (such as a picture preference test), the generality of deviant response patterns has been hypothesized (Berg 1955). The implications of this hypothesis and its empirical basis were critically evaluated by Sechrest and Jackson (1963), who expressed reservations about the claimed generality.

*Measurement and control of response sets.* Several different kinds of response sets have been isolated that are reliable and stable and that reflect varying degrees of generality. Their operation may either increase or reduce the reliability and empirical validity of scores. However, since they cause individuals with equal status on an ability or trait to receive different test scores, response sets seriously attenuate logical validity and complicate interpretations (Cronbach 1946). Thus, response sets tend to introduce errors of measurement that should be avoided and controlled.

Procedures for controlling response sets include (1) changing the test form to prevent their occurrence, (2) modifying directions to reduce their operation, and (3) using special response-set scores to correct for their influence (Cronbach 1950). If possible, response options with fixed categories, such as "true-false" or "yes-?-no," should be avoided in favor of multiple-choice or forced-choice forms. If fixed-response categories are used, the alternatives should be defined as clearly and as objectively as possible. Whenever the occurrence of a particular response set is thought likely, the instructions should be written to provide more structure and to reduce ambiguity. With regard to differences in guessing, for example, subjects should be specifically directed to answer all items (Cronbach 1950). In addition, special response set scores (Helmstadter

1957) may be used to correct for the set effect and to detect and discard subjects extreme in set responding.

On the other hand, some response sets appear to reflect important personality characteristics, and measures of these response styles may prove to be useful in their own right. When a response set is used as a measure of personality, the above control procedures should be avoided, and the test conditions should be designed to elicit the response set and to heighten its influence.

## RESPONSE SURFACES

See under EXPERIMENTAL DESIGN.

## RESPONSIBILITY

As a philosophical concept, responsibility is a correlate of freedom; as a political concept, it is a correlate of constitutionalism. Philosophically, the opposite of responsibility is external or internal compulsion; in political terms, it is arbitrariness.

It is necessary to distinguish between moral, political, and legal responsibility. *Moral responsibility* may be related only to consciousness; its extreme expression is Dostoevski's statement: "Everybody is guilty of everything." A clear example of such responsibility is the Stuttgart Declaration of the Evangelical church in Germany. Although no one blamed it for its attitude under the Nazi regime, the church made the following statement: "During long years we fought in the name of Jesus Christ against the devilish spirit of

which the terrorist regime of National Socialism was a terrible expression. Nevertheless we accuse ourselves that we did not confess more bravely, pray more faithfully, believe more joyfully, love more intensely." Moral responsibility may also have an objective dimension. According to John Stuart Mill, "A government is to be judged by its action upon men, and by its action upon things; by what it makes of the citizens, and what it does with them; its tendency to improve or deteriorate the people themselves, and the goodness or badness of the work it performs for them, and by means of them" ([1861] 1958, p. 28). Here moral and political responsibility are linked.

*Political responsibility* is more rigid than moral responsibility because it is judged by results and not by intentions. Political responsibility means the right use of power. It is relevant to both the tiny fragment of power in the hands of a single voter and the unlimited power of the dictator.

*Legal responsibility* is a fragile instrument of control because legislators and judges can easily misuse their political power by making laws and decisions weighted against political opponents. The ancient use of impeachment suggests how easily politics can be turned into law and law into politics.

The classic political expression of responsibility is found in Constant's *De la responsabilité des ministres* (1815). Although Constant's reasons for writing this book are now only of historical interest (the solemn impeachment power of parliament in cases of treason and embezzlement), he did develop three thoughts that still have fundamental meaning: (1) He replaced the notions of treason and embezzlement by the more general term "misuse of power." (2) He declared that in a constitutional monarchy a vote of no confidence by parliament must inevitably lead to the resignation of ministers. (3) He asserted the coresponsibility of lower executive officials who obey illegal orders.

### Fundamental concepts

The three statements above foreshadow the four main categories used in this article in the analysis of responsibility.

**Who is responsible?** Every member of the body politic is responsible according to his function, from the absolute ruler to the common voter. There are specific forms of political and legal responsibility attached to specific functions, e.g., to those of ministers and officials in constitutional states.

**How far does responsibility extend?** In the framework of a bureaucratic hierarchy, responsibility can be determined according to duties. The minister is responsible for his department, the

mayor for his city, the official for his office. The lower the position, the easier it is to define the limits of responsibility; until, at the lowest level, responsibility is limited to the execution of orders and directions. The higher the level of government, the harder it is to distinguish between the execution of laws and the exercise of discretion. In the jurisdiction of the German administrative courts the question of discretion is of great importance. After the excesses of administrative arbitrariness under National Socialism, an attempt was made to keep the field of discretion as narrow as possible. However, some discretion is necessary because efficient administration requires that each case be treated individually. Political responsibility in the broadest sense means responsibility to the public interest. The highest authorities—the sovereign people, the chief of government, the head of the state—are responsible not only for matters within their control but sometimes also for matters beyond their control, such as success or failure in war or in diplomatic negotiations. In former times, kings were held responsible even for starvation and floods. King Frederick the Great dismissed generals who were unsuccessful in battle. Public opinion tends to blame a political leader for not having mastered overwhelming odds. For instance, German political opinion held Chancellor Brüning responsible for the failure of the Weimar Republic.

**To whom is a man responsible?** Theoretically, the politician or administrator is responsible to those who gave him the mandate. His responsibility is in the first place to his superior in office and to the competent judge, who act as representatives of the sovereign; then to the sovereign; and finally to God. When the sovereign is the people, its judgment is expressed through public opinion, elections, or special tribunals. Often in primitive societies, the ultimate test of political responsibility is the ordeal.

**To which sanctions must the responsible person answer?** Legal penalties are adequate sanctions only if responsibility can be defined in legal terms. The politically responsible person can be dismissed only if he fails or has lost the trust of the person who commissioned him. The classic example is the dismissal of a minister after a vote of no confidence in parliament. Apart from this there are cases in which neither the field of competence nor the form of sanctions is fixed, but punishment is demanded by the disgraced monarch or the indignant people. Under these conditions sanctions may take the form of the "silk string" the despot sends to his vizier, of judgment by revolutionary tribunals, or of punitive measures by victorious enemies.

### Historical survey

One can speak of political responsibility only if there is a generally acknowledged standard for judging actions that affect the community; thus, political responsibility presupposes a kind of public interest. The history of political responsibility is simultaneously a history of the interpretation of public interest. In societies where a religious spirit dominates, public interest means adaptation to a divine order.

The emperor of China, for example, had to make certain that his empire found the middle path between heaven and earth. If the empire were permanently struck by misfortune, the emperor was considered to have lost his mandate from heaven; he was no longer a true emperor and could be—even had to be—deposed. Snorri Sturluson told of two Swedish priest-kings who were sacrificed to the gods in order to prevent starvation. A similar feeling for responsibility to fate was behind the Athenian institution of *ostrakismos*; a person could be banished arbitrarily, without imputation of dishonor, by vote of the majority. This was not meant as punishment for a crime, but merely to prevent some future misfortune that his continued presence might cause.

Medieval Christianity was the first to distinguish between several kinds of responsibility and between different authorities to whom responsibility was due. The church controlled the responsibility of the monarch to God. But it was a twofold responsibility. The prince had to lead a life beyond reproach in order to conform to the old idea that he personally represented the harmony of the political and the cosmic orders. At the same time he bore another responsibility, arising out of his political function: he had to dispense justice. The true nature of justice had to be determined by the public interest, which was conceived of as the best order for all or as a guaranteed order based on valid law. The absolute monarch was responsible only to God. Therefore, he was independent of the church as well as of the privileged estates. The doctrine of the "divine right of kings" included supremacy over the church. In the period of the Enlightenment the king himself separated the office from his person. Like Frederick the Great of Prussia, he thought of himself as the *premier serviteur de l'état*. The theory of the divine right of kings was upheld, but God was replaced by reason and justice as the recipient of responsibility. The king should be a *Staatskönig*; his authority was based on the idea of the state, but not necessarily on the consent of the nation.

Further changes in the concept of responsibility were introduced in the period of constitutional and parliamentary monarchies. Indeed, in these two systems the king was not responsible to anyone. In a constitutional monarchy such as Germany the ministers were responsible to parliament only for the legality of their actions. They did not need the confidence of parliament to stay in power; they needed only the confidence of the monarch. In England, a parliamentary monarchy, the ultimate decision on political responsibility rested in society itself, as represented by a full parliamentary convention.

The history of the modern state is also the history of the idea of public interest, proceeding from the privileges of the kings and the estates all the way to the *raison d'état* of absolutism. In continental Europe the *raison d'état* was generally embodied in the prince and his administrative and military staffs, and the public interest was represented by a well-ordered administration and well-ordered courts. In England the character of parliament changed; from representing the special interests of the different estates it came to represent the whole nation, and freedom became the standard of public interest.

The principle of popular sovereignty, through either representative or plebiscitarian democracy, has now been accepted all over the world. The constitutions of representative democracies contain a web of responsibility on different levels and a system of corresponding controls. Courts of justice examine whether legislation is within the limits of constitutional law and whether administration is exercised within prescribed bounds. Parliament controls the politics of the cabinet. In the same way it also controls the conduct of every minister responsible for a department. Public opinion controls the political style. Its organs are a free press, corporations of public or private law, and interest groups, spontaneous assemblies, or action groups. There is no immanent contradiction between representative and plebiscitarian democracy. But as soon as the plebiscitarian principle itself becomes an important factor, differentiation of responsibility is no longer possible. For in this case rulers and nation are declared to be identical, and the people itself takes over responsibility. Totalitarian regimes, therefore, often insist on being regularly legitimated by genuine or faked plebiscites.

### Types of responsibility and control

A distinction must now be made between the responsibility of a trustee and the responsibility of an agent. [See REPRESENTATION.] The trustee's

responsibility is personal; the agent's responsibility is technical. This distinction permits a consistent scheme for the different examples discussed. The leader of the state, whether a single person or a group, acts in the name of the whole body. Leaders can be regarded only as trustees of the whole—in a democratic society, as trustees of the whole nation. On the other hand, people responsible only for clearly circumscribed functions are mere agents. Their responsibility is limited by their instructions, provided that these instructions are in accordance with the constitution. A third and very important group consists of the leaders of the constituent sections or departments of the total power, for instance, members of legislative bodies, supreme courts, ministers as heads of the administration. In some of their duties they can be regarded as agents, but because they are more responsible for the spirit than for the manner of executive power, they are trustees. One might say that they exercise secondary trusteeship. In a democracy the distinction between trustee and agent vanishes. Even agents as a part of the sovereign people are regarded as—and may feel themselves to be—trustees. On the other hand, an authoritarian, and above all a totalitarian, government destroys any sense of trusteeship. This is illustrated by the attitudes of Hitler's and Stalin's highest functionaries, who hid behind orders and denied any personal responsibility, claiming to be only agents.

**Primary trustees.** The sovereign is responsible for the state as a whole. In democracies that responsibility is exercised through elections or plebiscites. There is no appeal against the decisions of the sovereign. It is a mutual responsibility of the people and their representatives; its standard is the spirit of the community. But there are exceptional cases, where responsibility is exercised by self-nominated agents of public opinion. Such exceptions may begin in rather trifling expressions of public uneasiness, as in the *Der Spiegel* affair in Germany in 1962. They can lead to a total change in the regime, as did *l'affaire Dreyfus* in France, and ultimately to a violent revolution, such as that caused by the protest of the French press against the royal ordinances in 1830.

The leader of the government, the head of the state, or the prime minister is also responsible for the whole destiny of a nation. He is legally controlled by parliament, by the voters, and indirectly by public opinion. He will be held responsible not only for misconduct, but also for bad policies, and in the last analysis for success or failure. The normal sanction is removal at the next election. Although other methods for removal are

available, their utility is doubtful; in the United States, for example, the institution of impeachment has never led to a conviction. The parliamentary committees for investigation, developed above all in German public law, may help to detect corruption, but they have no serious political effects. Decisions by supreme courts, e.g., the very influential Bundesverfassungsgericht (federal constitutional court) in Germany, are useful correctives for legislation and administration, but they do not provide sanctions against irresponsible behavior.

**Secondary trustees.** The importance of secondary trusteeship depends on the character of the government. It is considerable in a government with collective responsibility; it diminishes as a government approaches monarchy. Even under the same constitution it changes with the personal influence of the head of government and the minister concerned. In England the minister, as head of a department, is regarded as responsible for the conduct of his officials. Parliament will not remove him for minor blunders but probably will for mistakes seriously affecting men or institutions. In most cases the minister will resign quickly to save the government. In the United States the presidential system gives no opportunity to overthrow the government; the responsibilities of the departments and of their chiefs are sometimes not very obvious. So Congress uses other methods to get rid of unpopular officials: refusing to allocate funds, delaying bills, and so on. In the Continental systems the power of the bureaucracy as a semiautonomous body is so great, and is organized in such a way, that the main responsibility lies not with the parliamentary ministers but with the permanent secretaries of state or their equivalents. Here the special administrative courts are important means for compelling the administration to observe the intentions of the legislature.

**Agents.** The responsibility of agents consists in implementing constitutional provisions, making independent decisions of minor importance, and executing orders given by superiors. In the first two cases, the public is interested in internal control through the bureaucratic hierarchy itself and through administrative courts so that authority is not capriciously misused. The means of internal control are described by Carl J. Friedrich (1937, chapter 19) as (1) disciplinary measures, (2) promotional measures, (3) financial measures, (4) judicial measures, and (5) the spirit of craftsmanship. Friedrich makes the interesting observation that the appeal to *esprit de corps* is in some respects akin to the appeal to religious responsibility and affects the deepest strata of personality.

## Obedience and responsibility

The execution of orders given by superiors can give rise to serious conflicts. The official may be anxious to avoid a wrong policy because, as an expert, he can foresee serious consequences. In such cases the official should, according to Max Weber, "execute conscientiously the order of the superior authorities, exactly as if the order agreed with his own conviction. This holds even if the order appears wrong to him and if, despite the civil servant's remonstrances, the authority insists on the order" ([1919] 1946, p. 95). Responsibility in these instances is necessarily limited, and the official will resign only when he is convinced that the execution of the order would be dangerous for the state or would dishonor him.

Another source of conflict is the illegality of orders. In this case the official is not allowed to obey. When this occurs in a constitutional regime, it will be solved very quickly by appeals to parliament or by other legal means. The guilty superior will be reprimanded, and the disobedient official will be cleared. In authoritarian or totalitarian states the problem is more difficult. We still see Nazi officials trying to exculpate themselves with the claim of *Befehlsnotstand* (danger to their lives if they did not obey). Although the constitution and the special laws, and even military law, clearly forbid the execution of illegal orders, the culprits often justify themselves on the ground of imminent danger to their security and life. But personal responsibility must prevail even against obedience to political superiors. It is an important step in the democratic development of a people when the citizen's responsibility toward law takes precedence over his responsibility toward a superior.

## REVOLUTION

Revolution in its most common sense is an attempt to make a radical change in the system of government. This often involves the infringement of prevailing constitutional arrangements and the use of force. "Revolution" may also mean any fundamentally new development in the economy, culture, or social fabric—that is, in practically any field of human endeavor. In its modern (political) sense, the term was first used in the Italian city-states in the late Middle Ages, when it referred mainly to ecclesiastical reforms. The word first entered the English language in about 1600; under Cromwell, paradoxically, it came to mean the restoration of the old order. Traditional Spanish or Latin American *pronunciamentos*, Middle Eastern *coups d'état*, and the frequent upheavals in which one ruling clique replaces another, merely substituting one king, colonel, or courtier for another, without otherwise affecting the system of government or the fabric of society, cannot be considered revolutions unless, as has happened in a few cases, such upheavals are transformed into movements that bring about radical social change. On the other hand, it would be misleading to confine examination of the subject to the French and Russian revolutions, regarding all others as merely precursors of, or deviations from, these "classic" types.

Modern revolutions are usually carried out, according to their leaders, on behalf of the popular forces against despotism, corruption, and an outworn social and political order, and under the banner of progress, freedom, and social justice. Social movements, however, have to be judged not only by intentions, ideological declarations, and promises, but also by their actual performance. Some of those who take revolutionary action in the name of freedom and social justice are demagogues or impostors; others sincerely believe in these ideals but as a result of their actions may bring about a state of affairs that is a complete negation of their beliefs. Thus it is not always easy to distinguish between revolution and counterrevolution. The rise of totalitarianism has further obscured what was in the nineteenth century a seemingly clear-cut conflict between left and right. Condorcet's dictum that only movements striving for freedom can be truly revolutionary has become less and less tenable.

**The causes of revolution.** Despite the different patterns revolutions have followed, it is possible to trace certain features common to all. They usually follow the complete or partial breakdown of the old

order caused by the inefficiency of the governing class or by economic crisis, war, or similar happenings. Yet a "revolutionary situation" per se does not necessarily result in revolution; it may just as easily lead to anarchy or to a nonrevolutionary dictatorship if the revolutionaries (usually a conspiratorial group better organized than their rivals) are not capable of swift and decisive action.

The incident that sparks a revolution may be trivial: the performance of an opera of Daniel Auber's in Brussels in 1830; a student's cane dropping into the orchestra pit from a balcony in Munich in 1848; or the punishment by bastinado of a group of merchants in Tehran in 1905. The deeper causes, of course, go further back in time, and are more complex. Temporary economic crises have played a certain part in the outbreak of revolutions (the French famine of 1788, the bread riots in Petrograd before the February Revolution in 1917). However, left-wing French historians (Jean Jaurès, Georges Lefebvre) have doubted whether the economic crisis alone would have induced the masses to participate actively in the revolution of 1789, and communist historians, commenting on the year 1917, have attributed more importance to antiwar feeling than to food shortages.

War appears to have been the decisive factor in the emergence of revolutionary situations in modern times; most modern revolutions, both successful and abortive, have followed in the wake of war (the Paris Commune of 1871, the Russian revolution of 1905, the various revolutions after the two world wars, including the Chinese revolutions). These have occurred not only in the countries that suffered defeat. The general dislocation caused by war, the material losses and human sacrifices, create a climate conducive to radical change. A large section of the population has been armed; human life seems considerably less valuable than in peacetime. In a defeated country authority tends to disintegrate, and acute social dissatisfaction receives additional impetus from a sense of wounded national prestige (the Young Turks in 1908, Naguib and Nasser in 1952). The old leadership is discredited by defeat, and the appeal for radical social change and national reassertion thus falls on fertile ground.

Established elites and ruling classes have, however, also fallen in times of peace, for such reasons as sheer ineffectiveness, corruption, general boredom, or inability to adapt themselves to changing conditions. Corruption or extreme conservatism by itself, however, does not produce revolution. Despotism is often overthrown, not when they are being most tyrannical, but rather when

the established elite loses its self-confidence and starts making halfhearted attempts to become more liberal. The French Revolution of 1789 broke out after the States-General had been called; the revolution of 1848, after the unpopular Guizot government had fallen; the Hungarian revolution of 1956, after the surviving victims of extreme tyranny had been released. A united elite with a firm belief in the rightness of its cause has hardly ever been overthrown, regardless of the extent of its political, military, or economic setbacks. On the other hand, a comparatively minor reverse may prove fatal to an otherwise successful and reasonably competent elite that has lost its self-confidence and its will and ambition to rule.

A frequent source of revolutionary tension is the social unrest that may occur when a section of the population or a social class does not receive the political rights which it feels correspond to its value in society, when it faces a rigid structure or elite, or when its social and economic demands are not fulfilled. Oligarchies tend to defend their own privileges and to ignore the demands of a newly emergent sector or class, and as a result the "outsiders" despair of the possibility of gradual, peaceful change and conclude that only the complete overthrow of the old order will give them their rights and restore justice. In this context all revolutions, from the *secessio plebis* and Marius in ancient Rome to the French and Russian revolutions, are simply the culmination of long-drawn-out social processes; not the result of some sudden dissatisfaction of part of the population, but the last phase of a process of long duration.

In a similar way the rebellion of colonies against the metropolitan country and their eventual secession is a revolutionary process, made possible by the social, economic, and political development of the colony and the gradual evolution of a local elite.

Revolutions have a tendency to spread. Events in 1848 and 1918-1919 provide the best-known examples, but this generalization is also true of comparatively minor revolutionary uprisings. The Spanish revolution of 1820 (Rafael del Riego) indirectly provoked uprisings in Portugal (Bernardo C. Sepulveda), Naples (Guglielmo Pepe), and Piedmont. The French revolution of July 1830 had repercussions in Belgium and Poland. Many Asian and African countries gained independence after India had won hers in 1947. A revolution in one country frequently acts as a stimulus to revolutionary activity in another.

**The phases of revolution.** The stages of a modern revolution vary according to time, place, and the character and aims of the revolutionary group.

The activities of a group that has set itself limited aims, as in Mexico in 1910, differ from those of a party that stands for the total transformation of society, as in China in 1949. There are, however, certain features common to all but a very few revolutions.

*Prerevolutionary outbreaks.* Few revolutions come as a bolt from the blue: demonstrations, strikes, meetings, outbreaks of violence, a partial or total breakdown of law and order usually foreshadow the shape of things to come.

*Initial moderate stage.* After it has come to power, a revolutionary movement, being a coalition of various groups and parties, often assumes a moderate character. The exceptions are revolutionary movements that have come to power after a prolonged civil war and have decimated their enemies and rivals as a result of that war (e.g., Yugoslavia in 1945, China in 1949). Once the leadership of the former regime has been overthrown and the outstanding symbols of its rule removed, the new revolutionary regime is interested above all in "business as usual," in other words, the restarting of essential services, work in factories, shops, and on the land. A total breakdown would not be in the interest of the revolution, which usually lacks the qualified manpower to fill all key positions with its own candidates and therefore needs the cooperation of a substantial number of supporters of the old regime. Some genuine revolutionary movements fail at the first stage; Chu Yüan-chang came to power in 1368 as an agrarian revolutionary, yet could not carry out any radical reforms because he needed the assistance of the wealthy landowners to pay his army. Batista's Cuban uprising in 1933 differed from the traditional Latin American *coup d'état* and had the makings of a genuine revolution, since it placed sergeants over officers; yet its sole achievement was to enable the newcomers to share the spoils of the old system.

*Radical phase.* Revolutionary movements that outlast the first phase—both those which have more ambitious plans and those which are driven forward by the sheer logic of events—tend to adopt more radical measures in the second phase. At the same time the coalition of parties usually splits up, and the more radical elements (Jacobins, Bolsheviks) emerge as the sole possessors of power. Within the ruling group power passes into the hands of a very small number, often into the hands of a single individual. This process may be hastened by counterrevolutionary activities and/or foreign intervention, but it may also happen irrespective of such opposition. Every major revolution has destroyed the state apparatus it found and eventually

replaced it by setting up another, generally stronger bureaucratic organization in its place. This centralizing dictatorial trend has been marked in every modern revolution.

In many revolutions there are two distinct phases: the overthrow of the upper aristocracy in the English Civil War, for example, was followed at a later stage by the emergence of the middle and lower classes. The February Revolution of 1917 was followed by the Bolshevik seizure of power. Once the main revolutionary measures have been carried out and a certain normality re-established, there is frequently a change of guard. Some of the revolutionary heroes and leaders succeed in adjusting themselves to the new administrative and organizational tasks facing them; others do not and are cast aside, giving way to managers and bureaucrats. In the struggle for power that often ensues, it is by no means always the most radical leader who triumphs, but the better tactician, the man with the most support within the ruling group, the army, the police, or other power base.

*Postrevolutionary situation.* How do revolutions end? Some revolutionary movements fail at a very early stage or are beaten by the forces raised against them. Some of those that last longer peter out because a key leader dies (Oliver Cromwell) or because internecine strife undermines the revolutionary party (e.g., France in 1794). Others evolve over a long period of time and gradually change their character. Certain revolutionary achievements are maintained; others are slowly eroded, although the phraseology of the revolution is usually preserved. There are unlimited variations on this theme.

*The personnel of revolutions.* The typical nineteenth-century or twentieth-century revolutionary is of middle-class or lower-middle-class origin—student, young lawyer, or junior army officer. Elderly and very rich people or those with conservative inclinations are unlikely to lead or engage in revolutionary activity. There are, as usual, exceptions: the Brazilian revolution of 1889, which led to the downfall of the monarchy, was a movement of protest by leading *hacendados* against the abolition of slavery. The railroad disturbances in China in 1911, which led to the deposition of the Manchu dynasty, began as a protest of the principal railroad shareholders against nationalization. On the whole a revolutionary mentality is unlikely to flourish in such circles, although a number of aristocrats were on the side of the *tiers état* in 1789. The majority of leaders of socialist movements and of proletarian revolutions have been of middle-class origin; this fact suggests that the

feeling of frustration, the quest for power, the sense of injustice, and various idealistic aspirations are of greater importance in the formation of a revolutionary than is economic discontent. Oppressed nationality is occasionally an important factor (the high percentage of Jews, Latvians, Armenians, etc., in the initial stage of the Russian Revolution, the prominent part played by national minorities in revolutionary movements in the Balkans and the Middle East, the role of Poland in 1848, and so on).

In those parts of the world where grave social and political problems exist, higher education acts as a powerful stimulus toward revolution. The illiterate masses may be quiescent, however miserable their lot, but higher education provokes a "revolution of expectations" that cannot be fulfilled. Students and high school pupils have played a very prominent part in both the Russian and Chinese revolutions and in revolutionary movements in Latin America, the Middle East, and other parts of Asia and Africa; the fact that these were or are countries with a high proportion of unemployment or misemployment of university graduates is not accidental. The conflict of generations is another factor of considerable importance (the revolution of the *tenentes* in Brazil in 1939; of young army officers in Venezuela in 1945, in Egypt in 1952, and in Iraq in 1959).

Some revolutionary movements have been led and supported by one specific class or group (for instance, peasant revolts), but the major revolutions have had a broader basis both as to leadership and rank and file. Intellectuals have played a leading part in most revolutionary movements in Europe since the eighteenth century, while in many countries outside Europe young army officers have had a conspicuous role. The army as such in these countries is no more revolutionary in spirit than the police or the civil service, who on the whole play a passive part (or a waiting game) and regain importance only after the victory of the revolution; but as the principal source of physical power, the army is the most obviously effective instrument of revolution. Young revolutionaries in the Middle East and in Latin America have often chosen to become army officers because this career was the most likely to give them power and thus bring about political and social change.

Since, as a rule, a revolution can succeed only if preparations for it are kept secret, these have usually been confined to a small revolutionary high command. In the era before modern political parties came into being, an important part was played by secret societies, such as the clubs in France on

the eve of 1789 or the Chinese secret societies, which traditionally had great political influence (the White Lotus in 1775, the Society of Heaven's Law in 1813). A certain amount of conspiracy is involved in every revolution, but its ramifications are often exaggerated (the "hidden hand," the "conspiracy theory" of history) and undue importance subsequently attributed to certain bodies (the Illuminati, the Freemasons), attributing causal or organizational connection to events that were in fact quite unconnected. Apart from what is planned, there is in each revolution a spontaneous element, which is sometimes far more decisive. The revolutions in Germany and Austria in 1918 were neither foreseen nor planned by any revolutionary high command.

Revolutionary uprisings undertaken by the army are usually prepared by a single commander or a small group of officers (*junta*) having the support of a substantial part of the army. The garrison of the capital or the units stationed nearby are usually of decisive importance in this context. Twentieth-century revolutions in the more highly developed countries need a mass basis; the army may be essential for the initial stage, but different instruments are required to hold power and to carry out the changes deemed necessary. The more ambitious military usurpers have therefore tried either to collaborate with some of the existing political parties or groups or to create a political mass movement of their own (Perón, Nasser, etc.).

**Success or failure of revolution.** The factors determining success or failure in revolution are as various as the factors that generate revolutionary activity in the first place. The most frequent causes of failure are lack of support or active resistance by the bulk of the population and disunity or lack of purpose on the part of the leaders. In all modern revolutions the support of a militant minority and the physical seizure of some vital *points d'appui* (such as the seat of government, the army and police commands, the means of mass communication—radio, press, etc.) are decisive. These steps are carried out by a comparatively small minority and stand a good chance of succeeding if the group has mastered the elementary technique of the *coup d'état*, if the enemy is disorganized and incapable of counteraction, and if the bulk of the population is at least neutral. In the decisive first hours or days of revolution a few hundred, or at the most a few thousand, revolutionaries can achieve success even in a large country. (In the eighteenth and nineteenth centuries the pace was usually more leisurely.) Once a strong revolutionary dictatorship has been established, a comparatively small mi-

nority can retain power for a considerable time, provided that its policy does not antagonize all of the people for most of the time or permit the antagonized to organize. Technical progress in transportation and communication has made it much easier for such a regime to influence the whole population and control the entire territory, whereas in the past there was always a danger of counterrevolution breaking out in a remote part of the country.

The timing of a revolutionary attempt is of crucial importance; so are the personalities of its leaders. It is doubtful whether the October Revolution of 1917 would have succeeded without Lenin and Trotsky or indeed whether it would have been undertaken at all. The Bolshevik uprising succeeded, whereas communist or left-wing extremist revolutions elsewhere in Europe (Budapest, Munich) failed. Lenin's party was numerically stronger and better organized than the rather amorphous groups that supported the Bavarian and Hungarian revolutions; the ruling class was weaker and more discredited in Russia than in central Europe. In addition, counterrevolutionary action by foreign powers was, for geographic reasons, less effective in Russia than in Hungary and southern Germany.

A number of revolutions have failed because their leaders lacked the will and ability to persevere in a revolutionary course of action after the first demonstrations or fighting had taken place (Germany in 1848); they feared anarchy and radicalism in their own ranks more than they feared their enemies. Other revolutions failed because they were betrayed before the planned coups were carried out; since preparation is by necessity limited to a fairly small group, the arrest of some leaders can mean a lasting setback for a revolutionary movement.

**Counterrevolution.** Groups of people adversely affected (or likely to be so affected) by a revolution often band together to try to avert it or, if it has already occurred, to overthrow it. Support for counterrevolutionary movements in the nineteenth century usually came from the aristocracy, the clergy, or the higher ranks of the army—all those with a vested interest in preserving the old order. Toward the end of the century, however, and in particular after World War I, certain important changes took place. Since revolutionaries were appealing to the mass of the people and trying to establish, wherever possible, a mass basis of support for their activities, the counterrevolutionaries had to adapt to the new conditions. To have any political influence at all they were compelled to accept a part (sometimes a large part) of the revolutionaries'

program and to adopt their tactics. In Europe only those counterrevolutionary movements that have done so have enjoyed success for any length of time, although overwhelming outside assistance may serve as well. The counterrevolutionary movement usually restricts itself at first to mere demagogic phrasemongering; but gradually it spreads and gains a momentum of its own. The trade unions founded by Colonel Zubatov of the Russian police in 1900 were originally meant to combat the revolutionaries, but in the competition for popular support they gained a measure of independence, and their sponsors lost control over the movement. The fascist and national-socialist movements in Europe in the 1920s and 1930s usually began as counterrevolutionary movements; but the majority of their leaders did not belong to the old order and had no intention of restoring it. In their extreme forms these movements were quasi-revolutionary in character (National Bolshevism in Germany; Mussolini's Republic of Salò, etc.) or nihilistic (Hitler), rather than reactionary. The traditional categories of "revolutionary" and "counterrevolutionary" continued perhaps to make sense when applied to the more rudimentary forms of European fascism, but they became irrelevant in regard to its more advanced forms and to the totalitarian state in general. The Hungarian revolution of 1956 has proved this beyond reasonable doubt.

**Consequences of revolution.** It is characteristic of a revolution (in contrast to a mere *coup d'état*) that it has far-reaching political, social, and sometimes economic or cultural consequences. Revolutions have frequently been the "locomotives of history"; just as frequently they have been quite senseless, causing much unnecessary suffering. Revolutions have liberated peoples and elevated classes; at the same time some of the greatest crimes in history have been committed in the name of revolution. It has been argued that the emancipation of the third estate in France and the transformation of Russia into a democracy were already under way in 1789 and 1917 and that the revolutions merely gave a spectacular acceleration to an inevitable historical process. Since force begets force, however, violent revolution, though intended to overthrow despotism, very often culminates in a new tyranny. Since the idealism and devotion inherent in revolutionary movements thus serve to bring about a new despotism, the movements can hardly be regarded as great successes in terms of what they set out to do. Against this it is argued that the lasting "social achievements" of revolutions are more decisive than any short-lived "political distortion" or terrorism.

The major revolutionary movements of modern times have claimed a world-wide mission and have been expansive in character. The French Revolution in the years 1789-1815 undoubtedly helped spread civil liberties throughout Europe; some of its reverberations were felt in Europe and the rest of the world long after. Yet the attempt to bring the blessings of civil liberties forcibly to other countries produced a chauvinistic, antiliberal reaction in some parts of Europe, which had fateful consequences. Revolutions that set themselves limited objectives may succeed in achieving genuine reforms if they represent the aspirations of the majority of the population. The more violent a revolution, the greater the amount of coercion applied, the more likely that dictatorship, ostensibly established for a short "transition" period only, will be perpetuated. Revolutions that aim at a total transformation of society claim to act in the interests of the majority, but since the majority does not realize where its own best interests lie, it is left to a small avant-garde to make the decisions for it. In consequence it is more than likely that a society will emerge in which severe repression seems to be permanently built in. Such a state may achieve striking results in various fields, such as the national economy or national defense, but to judge from past experience, it will not succeed in building a freer and more just society.

**Doctrines of revolution.** The modern conception of revolution as a fundamental transformation dates back to the eighteenth century, although it is not quite correct to argue that the idea of a radical new beginning was altogether alien to ancient times. However, until the late eighteenth century the advocates of utopian societies were, with some notable exceptions, not revolutionaries, and revolutionaries were not utopians. Ordinarily, the revolutionaries fought against absolute monarchs or tyrants in the name of a natural order that the latter had violated. This tradition was expressed in the American War of Independence and the early stages of the French Revolution. The French Revolution produced an immense amount of theorizing on the subject, and the discussion received fresh fuel from the many revolutionary outbreaks of the nineteenth century. The famous exchange between Burke and Paine set the pattern for an argument which has continued to the present day. The conservative viewpoint rests on the belief that political and social continuity are essential prerequisites for an orderly society; that abstract rights and model constitutions count for little in practice; that revolutions are at best destructive and only replace one despotism by another—if they do not result in a

period of general anarchy. The nineteenth-century conservative regarded the revolutionary movement as inherently sinful, its leaders as misfits and criminals, and its followers as the deluded dregs of society.

Revolutionary theory in its more extreme forms, on the other hand, held that revolutionaries were only the most consistent fighters for freedom, justice, and the other ancient ideals of mankind and that therefore in the long run they could do no wrong. If conservative and liberal doctrine was largely based on a fear of violence, revolutionary theory belittled the significance of violence and terror and almost totally ignored the realities of political power in a modern society.

In recent decades the Marxist-Leninist doctrine of proletarian revolution has all but monopolized discussions on the subject. It claims to be a scientific doctrine and regards history as proceeding according to ascertainable laws. Revolutions fulfill a crucial function in the development of society: they overthrow the old social order, which has outlived its usefulness, and establish a new order; in this process power passes from the hands of one class (which is reactionary) to another (which is progressive in character). According to Marxist theory, the productive forces of society at certain stages of their development clash with the existing relations of production. The existing social order begins to impede their further development, and an epoch of social revolution begins. The basic problem in each revolution is the question of state power; through the class struggle power passes from one class to another. The class struggle may lead to civil war; its very highest form is revolution. All revolutions before 1917 only brought about the replacement of one form of exploitation by another; only the socialist (communist) revolution puts an end to man's exploitation by man. This is the final revolution, for in a socialist society there can be, by definition, only "nonantagonistic conflicts," conflicts that can be resolved in a peaceful way.

The historical fate of Marxist-Leninist doctrine is of great importance. It has been very successful, but not where it expected to succeed—in the industrially developed countries of Europe and North America. Instead it became the ideology of an industrial revolution in backward countries. The revolutionary situation that Marx had expected to develop in western and central Europe failed to arrive. In the underdeveloped countries, on the other hand, the Western impact produced strains that made for a different kind of revolutionary situation. These revolutions were not proletarian in character; neither in China nor in Cuba did the

working class take a prominent part in the revolution. These revolutions, however, brought to power regimes that were either communist from the first (China) or that soon adopted a "Marxist-Leninist" viewpoint (Cuba).

These historical fortunes of the Marxist-Leninist theory of revolution made various ideological mutations and adaptations necessary. The socialist parties of Europe became democratic in character; some of them continued to pay lip service to revolution, but their practice, and gradually their theory, became "revisionist." In the late 1950s several European Communist parties also began to show what some observers regarded as reformist inclinations. In Russia, Trotsky and others had propagated the idea of the permanent revolution, the doctrine that a "bourgeois revolution" in Russia (or a similar country) would immediately be followed by the establishment of a "proletarian dictatorship" and that an upheaval in one country would inevitably lead to revolution on a wider scale. The world revolution failed to materialize, however, and in the Soviet Union there developed what has become known (though never defined in detail) as the Stalinist concept of the "revolution from above." Revolution no longer meant the liberation of society from outworn political and spiritual fetters. Now it stood for the reshaping of society by a dictatorial regime controlling a centralized state apparatus and an all-pervading party organization. The "revolution from above" established communist regimes in eastern Europe; abortive revolutionary uprisings from below (Berlin in 1953, Poznan and Budapest in 1956) were later directed against these regimes.

Revolutionary movements continue to exist in the underdeveloped parts of the world; the revolutionary potential of these countries is far more pronounced than that of the industrially advanced nations. Revolutionary doctrine in these areas has absorbed some elements of the Marxist-Leninist theory, but to a very considerable extent it springs from other sources, such as resentment against the white nations that ruled the colonial world for so long. Attempts to organize the former colonies and underdeveloped countries into one united front against the metropolitan countries can be traced back to the 1920s, and in a somewhat modified form the idea has found new proponents in the 1960s; they argue that the underdeveloped countries are the "proletarian nations," the only truly revolutionary force on a world scale.

According to the Chinese communist thesis, revolutions (and wars of liberation) would and should continue regardless of consequences, whereas most Russian and European communists maintain that

in the nuclear age any large-scale wars of liberation could cause as much destruction as an imperialist war and have therefore become self-defeating as means of achieving political results. They argue that peaceful revolution has become possible as a result of a shift in the global balance of power and the growing attraction of the ideas of communism; the Chinese have violently attacked such views as revisionist.

The historical role of the Marxist theory of revolution has been enormous. With its emphasis on social and economic factors, it helped to put into wider perspective events that previously had been interpreted almost exclusively from a political angle; it has also been more useful than "static" interpretations as a guide to revolutionary situations. However, with the end of the epoch that produced it, this doctrine gradually ceased to be relevant; it ceased to be so in the communist countries because these faced, in the postrevolutionary situation, problems that could not be foreseen in the nineteenth century; it ceased to be relevant in the Western countries because there was virtually no likelihood of a revolutionary situation arising. In the *tiers monde* it continues to be of relevance as a doctrine of industrial revolution—one in which, however, national or local characteristics are of growing importance.

#### RICARDO, DAVID

David Ricardo (1772–1823), English economist, is best remembered for his theory of rent and his theory of comparative cost. He was the first to show that the ultimate incidence of a tax is governed by the laws of economic distribution, laws whose determination he regarded as "the principal problem of Political Economy."

Ricardo was born in London, the third child in a Sephardic Jewish family that had emigrated from Holland in 1760. At the age of 11 he was sent back to Holland to attend a special school, the Talmud Tora, attached to the Portuguese Synagogue in Amsterdam. He returned to London three years later to work for his father, who had become a successful member of the stock exchange. In 1793, against the wishes of his parents, he married the daughter of a Quaker, and they promptly disinherited him. Striking out on his own, he soon accumulated a small fortune as a stockjobber and loan contractor. In 1814, at the age of 42, he retired from business, purchased an estate in Gloucester-

shire, and began to devote himself to literary pursuits.

Ricardo's interest in economics dated back to 1799, when he accidentally came across a copy of Adam Smith's *Wealth of Nations*. Ten years later he made his debut in print with a newspaper article on the bullion controversy, subsequently expanded into a vigorous pamphlet entitled *The High Price of Bullion: A Proof of the Depreciation of Bank Notes* (1810; in *Works*, vol. 3, pp. 47-127). The Bullion Committee report, which appeared the following year, agreed with Ricardo that the current inflation was due to the Bank of England's failure to restrict the issue of currency. The fame of the committee's report lent prestige to Ricardo's tract, so much so that later generations incorrectly credited Ricardo with inspiring the report.

In 1814 he turned his attention to commercial policy and a year later published the important *Essay on the Influence of a Low Price of Corn on the Profits of Stock* (in *Works*, vol. 4, pp. 1-41). It appeared close upon similar essays by Robert Torrens, Edward West, and Thomas Robert Malthus. With varying degrees of clarity, all four pamphlets expressed the idea that was soon to become the cornerstone of classical political economy, the law of diminishing returns to additions of capital and labor applied to land. But only Ricardo went on to develop the implications of this proposition in a major treatise, *On the Principles of Political Economy and Taxation* (1817; see *Works*, vol. 1). The story of how he was urged, goaded, and even bullied into completing this task by his friend James Mill is now well known, owing to Piero Sraffa's recovery of the Ricardo-Mill correspondence, which is included in the *Works and Correspondence* (vols. 6-9).

Further tracts by Ricardo appeared in 1817, 1819, and 1822. In 1821 he published the third edition of the *Principles*, adding a controversial chapter "On Machinery," in which he conceded that technological progress might prove injurious to the working class (see BARTON, JOHN). In 1819 Ricardo obtained a seat in the House of Commons and for the next few years took an active part in parliamentary discussions of current issues. He made a grand tour of the Continent in 1822, keeping a travel journal, which is included in the *Works and Correspondence* (vol. 10, pp. 175-352). He died of a cerebral infection in 1823, at his estate, Gatcomb Park, leaving a wife and seven children. At his death his estate was valued at about £750,000, of which a third was in landed property and the rest in English and French government bonds (the present purchasing power of the estate would be approximately five times as much).

There never was an economist so single-minded in his devotion to "the dismal science" as Ricardo. He did spend some time studying the natural sciences, particularly geology—which then enjoyed something of the glamour that nuclear physics does nowadays—collecting minerals and participating in the management of the Geological Society of London. But with these exceptions, all his intellectual efforts were given to economics, and his correspondence rarely touches on other topics. Politically he was a Benthamite in that he favored universal male suffrage and as much parliamentary reform as was necessary to bring this about. If he had definite philosophical convictions, they were those of British empiricism as embodied in the works of Bacon, Hobbes, and Locke. He became a Unitarian after his marriage but was probably as near to atheism as Bentham was. There is reason to think that Ricardo followed James Mill in advocating the spread of birth control devices among the working class, although, unlike Mill, he never committed himself on the subject in print.

**Economic thought.** The influence of Ricardo's treatise made itself felt almost as soon as it was published, and for over half a century Ricardo dominated economic thinking in Britain. The leading periodicals and even the *Encyclopaedia Britannica* fell into the hands of his disciples; popular literature echoed Ricardian ideas; and Parliament increasingly succumbed to Ricardian policy proposals. Ricardo's appeal rested on his ability to seize hold of a wide range of significant problems with a simple analytical model that involved only a few strategic variables and yielded, after a few elementary manipulations, dramatic conclusions of a distinctly practical nature. In short, he was the first to master the art that later brought success to Keynes.

At the heart of Ricardo's system is the notion that economic growth must sooner or later be arrested owing to a scarcity of natural resources. In the simple version of his model, as expounded in the 1815 essay, the whole economy is a giant farm, distributing its product among landlord, tenant farmer, and hired laborer. The Malthusian tendency of population to increase up to the limits set by the means of subsistence provides a virtually unlimited supply of labor that can be employed at a constant real wage fixed in terms of corn (or wheat). This, of course, is the notorious "iron law of wages." Every worker is equipped with the same amount of fixed capital (say, a spade), which, being combined with every worker in the same proportion, enters as a simple multiple and, hence, can also be measured in terms of corn. In other words, corn is the only output of the giant farm,

and it is also the only input. As the labor force increases, extra corn to feed the extra mouths can be produced only by extending cultivation to less fertile land or by applying additional capital-and-labor to land already under cultivation with diminishing results. The difference between the net corn product per worker on the least fertile land and the constant corn wage per worker goes to the tenant farmer as profit. Since farmers outbid each other for the best land, the real advantages of working superior land accrue to the landowner in the form of rising rents. As more land is taken up, the net produce per worker falls, whereas the real wage remains the same. Obviously, profits per worker decline. At the same time, the corn value of the capital per worker increases because corn is continually becoming more expensive to produce in terms of real resources used up. Divide the falling profits per worker by the rising capital per worker, and it follows that the rate of profit on capital, which supplies the motive for investment, declines. Eventually, capital accumulation must come to an end.

In the *Principles* this simple one-sector model was replaced by a three-sector model, but the argument and the conclusions reached were essentially the same as in the essay of 1815. The three-sector model gave rise to the question how best to measure the variables employed, and the first chapter of the *Principles* turned into a veritable maze for the reader as Ricardo pursued "the invariable measure of value," which seemed forever to elude him. He failed to realize that an index-number problem such as he had posed cannot, in the nature of the case, be perfectly resolved.

The root of the trouble being the declining yield of wheat per acre of land, it is evident that the short-run solution is to import cheap wheat from countries better endowed with fertile land in exchange for low-cost manufactured goods. In the long run other solutions may be looked for: a change in workers' diets to lessen the dependence on wheaten bread; an effort to slow down the rate of growth of population; and, last, an attempt to foster technical change, particularly of the land-saving variety. Ricardo did not neglect these long-term solutions, but, it is fair to say, he dealt with them in a perfunctory manner. The fact is that despite the numerous references to capital accumulation and population growth, Ricardo's model is not really concerned with problems of economic growth in the long run. His interest in practical results—paradoxical in view of the high level of abstraction that he achieved—led him to emphasize the foreign trade solution to the growth dilemma. In so doing he came to attack the exist-

ing corn laws, which protected British wheat farmers by prohibiting foreign wheat except in years of famine prices. Eager to show that Britain would benefit from specializing in manufactured goods and importing the bulk of its food supply, he hit upon the law of comparative cost as a proof of his case.

Adam Smith had taught that it pays a country to concentrate on the production of those goods which it can produce more cheaply in absolute terms than any other country can. Earlier in the eighteenth century a few authors had advanced the wider rule that each country will find it profitable to import those goods which it can obtain for exports at less cost than their domestic production would entail. Almost no one realized that this meant that under free trade all goods are not necessarily produced in countries where their real cost of production is lowest—it might pay a country to import a product even though it could be produced at less cost at home than abroad. The Ricardian doctrine of comparative cost is simply a rigorous restatement of the informal eighteenth-century rule.

Ricardo used a single numerical example, involving two countries and two goods. He was able to demonstrate that it would benefit England to specialize in "cloth," even if Portugal could produce "cloth" and "wine" more cheaply, provided England had a relative cost advantage in cloth. And if Portugal specialized in wine, where it had an even greater cost advantage than in cloth, it turned out that both countries were better off: with given resources, both countries could enjoy more of both cloth and wine because they would reap the advantages of an international division of labor. Here is the fountainhead of all nineteenth-century free trade doctrine! Although the corn laws were not in fact repealed until 1846, Ricardo's writings helped to make free trade a popular objective of British policy. Unwittingly, Ricardo provided the theoretical justification for the long-run solution to the growth problem which Britain actually adopted in the nineteenth century: Britain became the "workshop of the world" and bought most of her food abroad.

Ricardo did much more than state the law of comparative cost. He also saw its implications for international wage and price levels. David Hume had shown earlier that each country's exports and imports are automatically brought into balance under an international gold standard by the effect of gold flows acting on domestic price levels. A country with an export surplus must attract gold from abroad; the gold inflow, by raising all prices within the country, then eliminates the excess of exports over imports. Similarly, an import surplus

leads to a loss of gold and a self-correcting decline in prices. Ricardo now realized that if Portugal has an absolute advantage in both wine and cloth but a great relative advantage in wine, foreign trade with England is possible only if money wage rates in Portugal are higher than those in England. If the wage rate in terms of gold is the same in the two countries, Portugal will not import cloth, since Portuguese consumers can get cloth more cheaply from domestic suppliers. As a result, England will be forced to ship gold to Portugal to pay for wine imports, and this will continue until gold wages and prices in Portugal rise enough to make it profitable for the Portuguese to import English cloth. In general, then, the low-cost country has the higher money wage rate, and hence higher money prices for similar goods. There is, as Ricardo said, "a natural distribution of specie" between the trading nations of the world that tends, in the absence of tariffs, not merely to equilibrate each country's exports and imports, but also to produce such relative price and wage levels between countries as to induce each to produce those goods in which it has a comparative advantage. And although the world is now off the gold standard, it remains true that everyone who has studied Ricardo's argument can understand why a high level of wages in a country does not necessarily prevent that country from competing successfully in international trade.

The same forces that depress the rate of return on capital in Ricardo's model also raise rents, although Ricardo never made it very clear whether he meant rents per acre of land or the rental share of the total product. Be that as it may, Ricardo viewed resources as shifting between agriculture and manufacturing in search of maximum returns, but he never conceived of land itself as shifting among competing uses. When, in the Ricardian model, cultivation is said to be extended, the new land is simply taken up freely, because land is treated not only as if it were completely fixed in supply but also as if it were absolutely specialized in use. It is this conception of land as a free "gift of Nature," having no use other than the production of wheat, that led Ricardo to the conclusion that rent is price-determined, not price-determining; in a famous formula, one of the many with which Ricardo peppered his otherwise pedestrian prose, "Corn is not high because rent is paid, but rent is paid because corn is high." From the notion that rent is not a reward for any economic service rendered by landowners, Ricardo drew the practical implication that the remission of rents from landlords to tenants would not affect the price of wheat or the rate of profit in agriculture. James Mill went a step further and concluded that the

appropriation of rents by the state would not affect agricultural output, a proposition that Henry George made his own when he called for taxing the "unearned increments" in rental values. The popularity of single-tax propaganda in the latter half of the nineteenth century did much to keep the name of Ricardo alive, and via Henry George's *Progress and Poverty* Ricardo even cast a shadow on the formation of the Fabian Society. In a period when the political power of the landowning aristocracy in England still barred the way to effective electoral reform, a theory that attributed economic difficulties to agricultural protection, asserting as a scientific conclusion that "the interest of the landlord is always opposed to that of the consumer and manufacturer," could not fail to take hold of public opinion.

While Richard Cobden and John Bright were adulterating Ricardo's arguments to suit the needs of the great campaign they were waging for immediate repeal of the corn laws, certain radical writers were putting forth labor's exclusive claim to the total national product, a claim which they argued was a simple logical deduction from the labor theory of value. These were the so-called "Ricardian socialists," forerunners of Karl Marx. The label is to some extent a misnomer, because these men, followers of Robert Owen, cared nothing for Ricardo except insofar as he sanctioned the labor theory of value. The notion that profit and rent constitute a deduction from values created by labor alone stems from *The Wealth of Nations*, not from Ricardo's *Principles*. Indeed, if by a labor theory of value we mean a theory that holds that labor is the sole determinant of relative prices, Ricardo cannot be considered a proponent of the theory. It is true that he believed that the ratios in which goods exchange are quantitatively more influenced by relative labor costs than by, say, relative interest charges. It is also true that he held a cost theory of value which left out the influence of demand. But this is still a far cry from what the Ricardian socialists and Marx himself meant by the labor theory of value. It never occurred to Ricardo to deduce anything about the nature of profit from his theory of value, and it is precisely this that separates Ricardo from Marx. But however misleading the common impression that Ricardo was responsible for the genesis of British socialism, the appeal to Ricardo by socialist writers, particularly the tribute that Marx paid him, gave Ricardo a new audience at a time when his influence was in other respects beginning to wane.

**Appraisal.** It is revealing to compare Ricardo to Adam Smith, the founder of classical economics. As a rigorous theorist, Ricardo was obviously far

ahead of Adam Smith. On the other hand, *The Wealth of Nations* contains more in the way of substantial generalizations on the workings of economic systems than does Ricardo's *Principles*—more, perhaps, than any other treatise written in the nineteenth century, with the exception of Alfred Marshall's *magnum opus*. If the problem of economics is the allocation of limited means among unlimited competing ends, as we are sometimes told, then Adam Smith contributed more to economics than did Ricardo; the only place where Ricardo addressed himself specifically to the allocation problem was in the chapter on foreign trade, but here, at any rate, he saw further and deeper than Adam Smith. If the problem of economics is growth and development—a common assertion nowadays—there is again more in Adam Smith than in Ricardo. But if economics is essentially an engine of analysis, a method of thinking rather than a body of concrete results, Ricardo literally invented the technique of economists. His gift for heroic abstractions produced one of the most impressive models, judged by scope and practical import, in the entire history of economic theory.

Ricardo's style of thinking is exemplified by his treatment of taxation, which takes up more than one-third of the *Principles of Political Economy and Taxation*. The discussion is very little connected with the actual taxes prevailing in his time, with the technical problems of tax administration, with the crying need for fiscal reform; instead, it traces the broad economic consequences of taxes in general with respect to the accumulation of capital, the distribution of national income, and the price level. The tax chapters simply set forth the general implications of Ricardo's theoretical scheme, and their value is solely that of demonstrating his superb logical powers.

As long as the corn laws remained in force, the issue of free trade gave significance to Ricardo's doctrines. When repeal came, John Stuart Mill's *Principles of Political Economy*, published two years later, brought new authority to the Ricardian system suitably amended. After 1870, however, most economists turned their backs on what they understood to be the Ricardian theory of value and agreed with William Stanley Jevons that Ricardo had "shunted the car of economic science to a wrong line" (1871). Marx's praise did not enhance Ricardo's reputation among academic economists. But the last decade of the nineteenth century saw a change in attitude, as a number of writers were suddenly struck by the idea that the old-fashioned Ricardian theory of rent was really a special case of a much more general theory. Ricardo had shown that the final dose of labor-and-capital on an in-

tensively used rent-yielding piece of land adds nothing to rent but consists solely of wages and interest, rent being due to the superior productivity of the intramarginal units. Philip Henry Wicksteed, Knut Wicksell, and John Bates Clark realized that there is nothing unique about a no-rent margin; when land is the variable factor and labor-and-capital is the fixed factor, the margin will be a no-wage, no-interest margin. With that insight the general marginal productivity theory of distribution was born, and to Ricardo's other accomplishments must be added that of having anticipated marginal analysis. In recent years concern over the problem of aggregate effective demand has caused many economists to agree with Keynes that "the complete domination of Ricardo's [approach] for a period of a hundred years has been a disaster to the progress of economics" (Keynes [1933] 1956, p. 33). But this is a harsh judgment which supposes that but for Ricardo's magisterial influence, economics would have addressed itself in the past to the macroeconomic problem of unemployment. Ricardo's avowal of the famous "law of markets," asserting a tendency toward full employment equilibrium, was poorly thought out and remained little more than a dogma. As a monetary theorist Ricardo was not even representative of the best work of his own day. Still, the law of comparative cost and the method of comparative static analysis have survived intact. And the central problem that Ricardo posed, namely, how the changes in the relative shares of land, labor, and capital are connected with the rate of capital accumulation, remains the abiding concern of modern economists. In that sense Ricardo is still with us.

## RICE, STUART

Stuart Arthur Rice is distinguished for his contributions to the growth of behavioral approaches in social science, to the progress of the United States government's statistical activities, and to bettering the relations between government and business. In particular, he improved statistical reporting, the organization of international statistics, and the collection of statistics in various foreign countries.

Rice received his Ph.D. in 1924 from Columbia University, where he studied primarily under Franklin H. Giddings. Sociological training at Columbia emphasized quantitative research, and Rice produced in the 1920s a series of pioneer studies (e.g., 1924; 1928) which used quantitative methods to test a number of hypotheses regarding political behavior. He hoped his studies would be models for an objective, empirical, value-free science of politics. One hypothesis he investigated

was that political behavior may be primarily the resultant of attitudes. He assumed that attitudes are normally distributed: abnormal distributions result from disturbing factors. He implied that political attitudes lie, for the most part, along one basic continuum of radicalism–conservatism. Along with William F. Ogburn and others, Rice used election statistics to analyze differences between various subgroups, thus anticipating later ecological voting studies. Following the leadership of A. Lawrence Lowell, he also used roll calls to detect differences between particular legislators and legislative blocs.

Another topic which Rice investigated in his early studies was the change over time in such political behavior as voter turnout and party preferences. He pioneered in the use of panel techniques to show the impact of observed stimuli upon the political attitudes of students, as measured by simple questionnaires.

At the time that Rice made his studies of political behavior, empirical research in social psychology was just beginning. L. L. Thurstone had not yet perfected his attitude-measurement techniques. Rice's use of the normal curve as a model of political behavior was soon outdated. More recently, social scientists commanding new data have elaborated his analysis of the areal distribution of political preferences. Again, the sample survey of the general population has replaced Rice's indirect inferences with the direct measurement of both actual voting and the individual characteristics of citizens. Yet, considering the tools available in the 1920s, Rice made a notable attempt to show the possibilities of an empirical approach to the study of political behavior.

Rice compiled, under the auspices of the Social Science Research Council, a critical review of the methods employed in the social sciences (1931). Case studies of the methods employed in outstanding contributions to social science were arranged in a theoretical setting designed to portray different methodological approaches, without regard to traditional boundaries in subject matter. The basic classification of methods was devised by Rice, as chief investigator and editor, with the assistance of Harold D. Lasswell.

Rice then turned from research and teaching to administrative work in the federal government. Here he did much to professionalize the activities of the Bureau of the Census. He also made notable contributions to the development of social statistics in the United States, the study of the effects of unemployment, the analysis of world standards of living, the establishment of a rationalized sys-

tem of federal statistics, and the projecting of the statistical needs of the United Nations.

Rice was born in northern Minnesota in 1889. He attended the University of Washington, obtaining his B.A. there in 1912 and his M.A. in 1915, and was employed for some years in welfare administration at the local, state, and regional level. After an unsuccessful venture into minor party politics in 1920, he became interested in exploring the rational character of social movements and pursued the objective analysis of sociological data at Columbia University. He taught at Dartmouth College from 1923 to 1926 and at the Wharton School of Finance and Commerce of the University of Pennsylvania from 1926 to 1933.

His first appointment in Washington was as assistant director of the Bureau of the Census, a position he held until 1936. As president of the American Statistical Association in 1933, he was influential in creating the advisory services which in turn produced the central administrative structure for the development and coordination of the federal statistical system. For nearly two decades he was director of the Office of Statistical Standards of the Bureau of the Budget, charged by law with control of statistical work within the government. He won wide praise from the business community for his successful endeavors to reduce the reporting burdens imposed by federal questionnaires. At the beginning of World War II, Rice instigated the creation of the Inter-American Statistical Institute, which supplies the statistical staff of the Pan American Union. At the end of the war, he was active in the establishment of the Statistical Office of the United Nations and served as the first chairman of the UN Statistical Commission, where he displayed skill and ingenuity in working toward greater adequacy and comparability of world statistics.

As president of the International Statistical Institute from 1947 to 1953, he promoted collaboration among the world's statisticians and at the same time pointed out that the conceptions of statistics in the Soviet Union were an impediment to the growth of international statistics. As head of the Statistical Mission to Japan, he helped develop the statistical services of that country. Upon retiring from federal service in 1954, Rice organized and became president of the Surveys & Research Corporation, a consulting firm offering economic, statistical, and management services to United States and foreign governmental agencies, as well as to private industry and nonprofit organizations.

HAROLD F. GOSNELL

#### RICHARDSON, LEWIS FRY

Lewis Fry Richardson (1881-1953), British meteorologist and student of the causes of war, was born at Newcastle-on-Tyne, the youngest of seven children in a Quaker family. He attended the Newcastle Preparatory School, then Bootham School at York. His inclination toward science seems to have been inspired by J. Edmund Clark, a master at Bootham School, who was a meteorologist. However, while still in his teens, Richardson was convinced that "science ought to be subordinate to morals." After leaving Bootham in 1898, he attended Durham College of Science at Newcastle, then King's College at Cambridge.

Several appointments followed, each of short duration. Richardson worked as an assistant in the National Physics Laboratory, as chemist for a peat company, and as director of the physical and chemical laboratory of a lamp company. At the outbreak of World War I he was superintendent of Eskdalemuir Observatory of the Meteorology Office. Thenceforth, meteorology became one of his abiding scientific concerns, and he contributed some thirty papers and a book (1922) to that field.

In 1926 his scientific achievements were recognized by his election as fellow of the Royal Society.

For Richardson, Quakerism is firmly identified with pacifism. Accordingly he declared himself a conscientious objector, a stand that subsequently barred him from university appointments. Nevertheless he participated directly in the war in a non-combatant capacity, as a member of the Friends' Ambulance Unit, attached to the 16th French Infantry Division. After the armistice he returned to the Meteorology Office, but in 1920, when that office became part of the Air Ministry, Richardson resigned his position. He next took charge of the physics department at Westminster Training College and in 1929 became principal of Paisley Technical College and School of Art, his last post. Richardson retired in 1940 in order to devote all of his time to the study of war, searching both for its causes and for means to prevent it [see WAR, *article on THE STUDY OF WAR*].

It is with his work on war that Richardson's name is most frequently associated. Although his pacifist convictions were surely a source of his dedication to this study, on which he spent at least 35 years, it is likely that his deep involvement with meteorology influenced his method of research. The prediction of weather is notoriously difficult, even though the determinants of weather are entirely understood. The principles governing the several variables—the motion of air masses, the changes of pressures and temperatures, the onset of precipitation—are all known, but the interactions among all these factors are so complex that even if the atmospheric conditions over the globe were precisely known at a given moment, the calculation of future states for even a short period would be a superhuman task. At one time Richardson estimated (1922) that it would take 60,000 human computers working at high speed to compute tomorrow's world weather charts before tomorrow's weather arrived. The vital lesson that Richardson therefore learned from the problems of meteorological prediction—one that has been confirmed by modern computing technology—is that events which seem to be governed by chance (as does the weather to one ignorant of the dynamics of air masses) are in fact governed by laws and can be predicted if enough information can be processed.

The link between this insight and Richardson's approach to the phenomenon of war is in his rejection of the idea that war is a rational, or at least a purposeful, form of behavior, as is often assumed in the conventional political conception of international relations. Richardson viewed war

instead in Tolstoyan fashion, as a massive phenomenon governed by forces akin to the forces of nature, over which individuals have little or no control. Accordingly, he ignored all those intricacies of diplomatic-strategic analysis usually pursued by political historians and turned his attention to quasi-mechanical and quantifiable processes which, he assumed, govern the dynamics of the international system of sovereign states. Neither the contents of memoranda and ultimatums nor dynastic claims, territorial ambitions, and networks of alliances play an explicit role in Richardson's theory of war. Instead, one finds differential equations purporting to represent the interactions among states or the spread of attitudes and moods (like the spread of communicable diseases) among the populations of those states. The equations are quite similar to those representing physical or chemical systems, at times tending toward equilibria, at times moving away from equilibria at accelerated rates and culminating in explosions.

Richardson harbored no illusions concerning the adequacy of his mathematical theory in providing an "explanation" of war, much less a means of preventing it. In omitting strategic calculations, considerations of prudence, and other "rational" factors as determinants of war or peace, he was not asserting the irrelevance of these factors. Rather, he sought to build a viable theory of war *in vacuo*, as it were, an admittedly crude but tractable model upon which a more sophisticated theory could be developed. "The equations are merely a description of what people would do if they did not stop to think," he wrote (1960a, p. 12). Some of his equations did fit what actually happened in the years preceding World War I, and Richardson concluded that the Great Powers in that instance were acting as if they were driven by mechanical forces.

In spite of the formal, mechanistic character of the equations that Richardson proposed as a model of international relations, he thought of the causes of war as primarily psychological. The underlying psychology was that of a mass, much simplified by the averaging out of the many opposing pressures, devoid of self-insight or foresight; it was not the psychology of an individual, with a large range of choices, moral convictions, and idiosyncratic preferences. Richardson's first paper in this vein was entitled "Mathematical Psychology of War." Written in 1919 and privately printed, it was not published until 1935. In the intervening years Richardson studied psychology as an external student of University College in London, receiving the special B.Sc. degree in 1929. His work in psychology is

strongly oriented toward the quantitative approach, and some of it shows the same influence of the "meteorological orientation" as do his studies on war (1937).

Richardson published the complete version of his mathematical theory of war, *Generalized Foreign Politics* (1939), on the very eve of World War II. Its point of departure is a pair of differential equations representing a hypothetical interaction between two rival states. The components of interaction are (1) mutual stimulation of armaments buildup, assuming that each nation's rate of increase of armaments expenditures is positively proportional to the other nation's current expenditures; (2) self-inhibition of armaments, assuming that the rate of change of armaments expenditures is negatively proportional to the already existing armaments burden; and (3) constant stimulants to armaments buildup in the form of grievances or ambitions of states. These latter may also be negative, in which case they are interpreted as reservoirs of good will. Cooperation between the rival states, for example, in the form of trade, is interpreted as negative armaments expenditures.

Richardson then examined the dynamics of the postulated system. The solution of the equations (given the initial conditions and the parameters of interaction) determines the time course of the armaments expenditures. By substituting selected values for the parameters, Richardson was able to obtain a good fit of the predicted time course for the armaments buildup of the rival European blocs (the Central Powers and the Entente) in the years preceding World War I. However, the large number of free parameters and the small number of points representing the time course make this "corroboration" of the theory less than impressive.

Of considerably greater interest is the theoretical result deduced from the model, namely that depending on the relative magnitudes of the stimulation and inhibition parameters (but not of the grievance-good-will parameters), the system may be either stable or unstable. If the parameters are such that the system is stable, then an armaments balance is possible (this might also be interpreted as arms control). However, if the parameters are such that the system is unstable, then such a balance is not possible. The system must move one way or the other, depending on the initial conditions, either toward total disarmament and beyond to ever-increasing cooperation or into a runaway race, presumably followed by war.

By noting the rate of disarmament of Great Britain following World War I and the rate of rearmament of Germany prior to World War II,

Richardson was able to get rough estimates of the parameters in question. He concluded that the parameters were well within the region of instability and, moreover, that the initial conditions prior to World War I made it touch and go whether the system would move toward peace or war. Possibly just a slightly lower armaments level or just a little more interbloc trade would have pushed the system toward a united Europe instead of toward world war [see DISARMAMENT].

Following the analysis of the arms race of 1908-1914, Richardson attempted to analyze the similar process that started shortly after Hitler's rise to power. The disappearance of the gold standard as a basis for the measure of expenditures and the scantiness of data from the U.S.S.R. made the analysis of the arms race preceding World War II extremely difficult, beyond anything that a lone investigator could accomplish in a lifetime. Still, Richardson's theory of the mutually stimulating arms race did point to a second world war.

Whether or not these conclusions ought to be taken seriously is a difficult question. Certainly, controlled experiments on the scale of international relations cannot be brought to bear on the critical aspects of Richardson's theory. Yet whatever the explanatory or predictive merits of the theory, one cannot deny that it invites us to see the phenomenon of war from an unusual point of view. This point of view may have been stated earlier (Richardson cites Thucydides as a proponent of the mutual stimulation theory of arms races and wars), but the quantitative implications of rigorously formulated models based on this view seem never to have been worked out.

Besides the two-nation problem of mutual stimulation in an arms race, Richardson also posed the N-nation problem. Again, the relevance of his results to real international dynamics is an open question because of the vastly simplified assumptions on which his models are based. Nevertheless, the results are interesting, not because of the answers they provide but because of the questions they raise. Thus, Richardson found, for example, that in an arms race involving three nations, the situation can be stable for each of the three pairs separately but unstable for all three taken together. This result may be relevant to the currently acute N-nation nuclear force problem [see NUCLEAR WAR].

Following his retirement in 1940, Richardson started extensive empirical investigations. He performed the monumental labor of gathering a vast variety of data related to all "deadly quarrels" that have been known to occur since the end of the

Napoleonic Wars. Richardson's treatment of the data again reveals his view of war and of violence in general as something with which the whole human race is afflicted. This view is diametrically opposed to that represented by strategic thinkers and most clearly expressed by Karl von Clausewitz, who saw war as an instrument of national policy and a normal form of intercourse among civilized states [see CLAUSEWITZ].

To Richardson, war is a particular case of a "deadly quarrel," defined as a violent encounter among human beings resulting in one or more deaths. He placed all such encounters on a scale of magnitude (defined by the logarithm of the number of dead). Thus, single murders appear on this scale as deadly quarrels of magnitude 0 ( $\log_{10} 1 = 0$ ), small riots with some ten victims as deadly quarrels of magnitude 1 ( $\log_{10} 10 = 1$ ), and so on. The two world wars appear on this scale as deadly quarrels of magnitude 7.

Richardson sought to establish a relation between the magnitudes of deadly quarrels and the relative frequency of their occurrence, analogous to the relations established by George K. Zipf (1949) between ranks and sizes of a great variety of objects [see RANK-SIZE RELATIONS]. But unlike Zipf, who singled out the rank-size relation as a unifying principle of fundamental importance, Richardson treated this relation as one of many to be examined in the search for regularities from which, he hoped, the laws governing human violence would emerge.

Richardson sought to relate the frequencies of wars not only to their magnitudes but to every other conceivable factor that could be extracted from the data. He examined the effect of the existence of common frontiers between the combatants and of the existence of a common language, of a common religion, and of a common government (as in civil wars). He made a list of all the "pacifiers" that have been supposed at one time or another to counteract the tendency to violent outbreaks, such as distraction by sports, diversion of hatred to other groups, the direction of hatred inward, armed strength as a deterrent, collective security, or intermarriage among potentially hostile groups. None of the indices related to these pacifiers shows up as a significant contributing factor either to the likelihood of a "deadly quarrel" or to its prevention. Possible exceptions are international trade and allegiance to a common government. Thus, hardly anything in the way of new knowledge as to the "causes" of wars has emerged from this monumental analysis, unless one views as new the refutation of established notions by negative

results. In particular, neither armed might nor collective security measures (contrary to widespread opinion) emerge as significant war-preventing influences.

The failure of the "statistics of deadly quarrels" to generate a theory on the causes of wars was to be expected in view of the magnitude of the problem. Because Richardson worked alone and had no access to modern computing machinery, the bulk of his effort was absorbed in tedious data gathering and routine calculations. It is likely, of course, that any crudely empirical brute-force attack on the causes of wars is inherently doomed to failure. The nature of the primary contributing causes may be shifting rapidly and may be quite different in different cultural milieus, so that lumping together all the deadly quarrels in the world for a period of some 120 years may be statistically meaningless. Still, the pioneering significance of this work and Richardson's gallantry in attacking the formidable problem singlehanded should not be underestimated. Whatever conclusions he drew or failed to draw, his work remains a rich collection of data.

Two of Richardson's books were published in 1960, under the titles of *Arms and Insecurity* and *Statistics of Deadly Quarrels* (1960a; 1960b). The former, edited by Nicolas Rashevsky and Ernesto Trucco, contains Richardson's mathematical theories of arms races, worked out in great detail, and the data relevant to those theories. The latter, edited by Quincy Wright and C. C. Lienau, contains the analysis of the voluminous data on violence ranging from murders to world wars. The two books were widely reviewed and helped establish Richardson's reputation as the pioneer of research into the causes of war.

Following the publication of these two books, a number of investigators in England and the United States undertook to combine Richardson's methods of mathematical model construction and data analysis in the field of international relations. In particular, content analysis methods have been used in attempts to obtain indices of international hostility; various attempts have been made to extend Richardson's theory of arms races to cover the present period; and his methods of correlation analysis, designed as a search for the causative factors of wars, have been modified and refined. In Volume 8 of *General Systems* some of these investigations were published or reprinted under the heading "After Richardson" (Rummel 1963; Smoker 1963).

The principal value of Richardson's contribution lies in the idea of bringing quantitative analysis to

bear upon the possible massive system-dynamic determinants of war. His work stands at one end of a spectrum, the other end of which is represented by game-theoretic analysis, where it is supposed that international relations can be viewed as interplays of strategies calculated by "rational players." This latter view is by far the more prevalent among political scientists. Richardson's quasi-deterministic view of international relations is complementary to the strategic view, which assumes rationality in the pursuit of "interests" but leaves unanalyzed the genesis of the interests. The strategic view may inquire how nations conduct (or would conduct, if they were rational) a diplomatic-military game but says nothing about how the game got started, why enmities are built up between some states and not between others, or, of course, why states behave so frequently and so clearly against their own interests. Although Richardson did not shed much direct light on these matters, his approach raises important questions that are too often ignored in the purely diplomatic-military approach to international relations.

#### RITTER, CARL

In his own time Carl Ritter (1779-1859) was one of the best-known German scholars in the world. For the few who are still aware of him, his voluminous writings of more than 25,000 pages are a mine of facts and perspectives. The most widely read biography, written by his brother-in-law, Gustav Kramer (1864-1870), considered him in strictly theological terms; and as a consequence, the Positivists who followed condemned him, without examining whether his religious beliefs in fact distorted his scientific work. Nevertheless, Ritter, with Alexander von Humboldt, is still generally considered one of the founders of modern scientific geography.

Ritter's life encompassed the German Enlightenment, romanticism, and the Biedermeier era, and—more clearly even than in Humboldt's case—his work mirrored his active participation in all the intellectual movements of his time. He considered it providential that he found himself repeatedly in the center of contemporary intellectual controversies.

His father, an outstanding diagnostician who was personal physician to the sister of Frederick the Great, died in 1784, leaving his widow, a devout Pietist, with six children and in straitened circumstances. In the same year, the well-known pedagogue Christian G. Salzmann had founded his Philantropinum in Schnepfenthal; since he was unable immediately to find pupils, he admitted on scholarships two boys who seemed to be highly talented—Carl Ritter and his brother Johannes, as well as their tutor, Guths Muths. For 11 years,

longer than any other pupil, Carl remained at that institution of sober enlightenment, which neglected humanistic studies—stressing instead the development of such tangible values as a sound body and a good character—and which was designed to produce not scholars but citizens.

Since Ritter showed a talent for drawing, Salzmann planned to make him a copperplate engraver, but chance gave his life a different direction. The Frankfurt banker Bethmann, an ancestor of the German Chancellor Bethmann-Hollweg, happened to be in Schnepfenthal. He hired Ritter as a tutor for his two boys, first sending him for a few years to the University of Halle to fill in any gaps in his education in general and to study cameralism in particular. The Bethmanns remained Ritter's benefactors until he became self-supporting.

Ritter's main initial interest was pedagogy, which brought him into close contact with Johann Heinrich Pestalozzi. He became not only one of the most knowledgeable interpreters and critics of Pestalozzi's "method" but was also chosen by Pestalozzi to succeed him at Iferten; when Ritter refused, his friendship with Pestalozzi came to an end.

Even in his pedagogic period, which lasted from his entry into the Bethmann household until the start of his studies in Göttingen (from 1798 to 1813), Ritter had become interested in geography. His early work, *Europa: Ein geographisch-historisch-statistisches Gemälde* (1804–1807), was still completely under the influence of the then-current statistical political science. However, in the atlas *Sechs Karten von Europa* (1804–1806) that accompanied his work, he revealed his ability to envision the continent as a whole. These maps conceive of the elements of an area as layers: the surface, vegetation, cultivated plants, animal life, population and tribes, etc. He intended the atlas merely as an educational aid for schools, yet it was the origin of the kind of cartographic documentation that is commonly used today.

Ritter's thinking and his scholarly aims were strongly influenced by travels through the magnificent Swiss landscape and by his contacts with Pestalozzi and the theologian Johannes Niederer. He came not only to appreciate the individual character of various kinds of scenery and to develop the idea of interaction between nature and culture, but also to see it as his mission to explore this idea of interaction for the benefit of mankind.

Pestalozzi fostered these general ideas by acquainting Ritter with the idea of a "type," and by suggesting that this concept of type be introduced into the field of geography in a textbook for his

school. There was a strange contradiction in Pestalozzi's predilection for types and his radical condemnation of definitions, which he considered as abstract and therefore lifeless and rigid. For Pestalozzi the only adequate definition was a complete description, and Ritter's later works show that he accepted this view.

Niederer awoke Ritter from his cool, rationalistic moralism to a deeply felt Christianity, though he did not at once become a member of a particular church. Ritter searched for a suitable intellectual foundation for his Christian views, for instance in the works of Friedrich Schleiermacher, and only much later, in Berlin, did he become a Lutheran.

When Ritter submitted to the famous geologist Leopold von Buch the manuscript of the textbook on geography that he had promised to Pestalozzi, it was criticized so severely in its details that Ritter scrapped it. Instead he undertook to incorporate all the known details of geography in a vast description of the entire earth, hoping ultimately to produce the general geographic textbook suggested by Pestalozzi.

In 1813 Ritter went to the University of Göttingen as a tutor to the Bethmann boys and to pursue his own academic plans. Göttingen was at the time the only intellectually free institution in Germany, where research without censorship or tutelage was possible, and it was therefore the gathering place for an elite. Although Ritter did not participate actively in university affairs, he came into contact with the leading men there, such as the anatomist and polyhistorian Johann Friedrich Blumenbach, who played a role also in the development of geography and anthropology; the historian Arnold Heeren; the anatomist Samuel Sömmering; and the mineralogist Hausmann. His contacts extended to Berlin, where the jurist Savigny and the theologian Schleiermacher were his friends. All of these, as well as earlier friends, such as August von Schlegel, Baron Karl vom und zum Stein, and Madame de Staël, were connected with the romantic movement.

In response to new intellectual currents, Ritter studied the entire literature on geography from ancient times to contemporary travel descriptions and made excerpts from it, in order to gain for geography a clearly defined sphere within the sciences and a body of problematics. The principal subject matter for further study was, as he saw it, the surface of the earth from the time that man began both to influence the development of the world and to be influenced by it. This means that geography for Ritter was the science of the surface of the earth in its material utility, and especially

in its interaction with the people who populate it and develop their cultures on it.

The year 1817 saw the publication of the first volume of his *Die Erdkunde im Verhältniss zur Natur und zur Geschichte des Menschen* . . . ; after he had completed the second volume (1818), he began a second edition, which by the time of his death had grown to 21 large volumes dealing with all of Africa and Asia, except for a small western portion of Asia Minor.

The originality of this book soon was acclaimed all over the world, and it also attracted the attention of the Prussian general staff and of those who were responsible for the re-establishment of the University of Berlin. Both groups joined in calling Ritter to Berlin in 1820, to teach geography at the university and to instruct the Prussian military leadership corps. His success in teaching was considerable, although its full impact cannot be judged without further research. The most important German generals, especially Roon and Moltke, were his closest students; they wrote valuable textbooks and reports and applied in practical strategy what Ritter had taught them. At the university, he found enthusiastic and productive disciples among many historians and among such geographers as Heinrich Kiepert, J. E. Wappäus, Heinrich Berghaus, Heinrich Barth, and Elisée Reclus. For all his self-confidence Ritter was modest and reserved, and his public appearances were confined to numerous congresses at home and abroad; he disdained taking advantage of his position as instructor in geography and history to the Prussian princes and princesses to further his personal social position. Nevertheless, the intervention of friends, particularly that of Alexander von Humboldt with the king, permitted him almost every year to undertake long and at that time still very difficult travels throughout nearly all of Europe. Beautifully written travel reports (see G. Kramer 1864–1870, part 2) give testimony to his skill in observing scenery and people and disprove the general opinion that he was a mere bookworm. He was active until he died at the age of 80, soon after his friend Humboldt.

**Evaluation.** What remains of Ritter's work is, first of all, his capacity to perceive a geographic entity and geographic relationships and so to develop the study of regions instead of the traditional study of states. The fluctuating boundaries between states meant little to him, since he described each area in terms of the actual changes that have gradually been established by science. He sought to develop a new and more meaningful organization of the earth into regions, based on intrinsic sources of coherency. These regions might be, for example,

river basins, plateaus, or terraced areas. They are parts of the larger units of the total earth organism, that is, of the continents. To establish these lesser units, it is necessary to have an accurate topographical map and as complete a description as possible of the landscape in a given area, as well as of the climate, the vegetation, the animal life, and finally of man and his historical interaction with the foregoing elements. Clearly the fundamental idea is that all these elements are interconnected and that their differential regional occurrence and interaction determines the character of a particular area.

The human population of a specific area was what aroused Ritter's particular interest. He considered man the fulfillment of creation and its ultimate purpose. Geography, he believed, would fail in its central task if it did not understand how man influences the space in which he lives and is in turn "educated" by the advantages and obstacles that the space offers. Ritter devoted special attention to the period of the greatest cultural development of each area, since he believed that in such periods the highest degree of harmony between nature and culture can be assumed to exist. Thus he became the founder of the kind of historical study of regions that only recently has been seriously revived.

Geographers no longer adhere to Ritter's method of revealing to the reader all the sources of their material. Ritter has been criticized for succumbing to the weight of his sources, for not being able to discriminate the essential. This criticism overlooks the fact that it was he who introduced into geography the critical review of contradictory sources and that he presented clearly the concept of the persistence or change of certain elements in the geographic-historical development of the areas he described.

The romantic principle of "polarity," long since abandoned by geography, permitted Ritter to discover such polar relationships as those between the hemispheres of land and water, between central and peripheral areas, between oceanic and continental phenomena in all their possible natural and historical variations, and between the climatic zones within the polaric tension of north and south. Also, from romanticism came Ritter's concepts of "individuality" as applied to units of space and of "organism," applied to the earth as organism. In Ritter's view this meant more, however, than that the whole is greater than the sum of its parts—an idea that has been revived by the new science of geography in its concern for the "integration" of all parts.

Ritter took a unique position with regard to the natural philosophical conception of the earth as based on a plan that was conceived at creation and that classifies all things according to their endowed ability to develop. (This position is fully developed by Henrick Steffens in his *Anthropology*, published in 1822.) Ritter did not reject natural philosophy a priori as did Humboldt and the majority of scholars at that time; indeed, he was rather inclined toward it. But he refused to acknowledge its claim to being a superior kind of science, based on the specialized sciences it scorned. Avoiding both extremes, he endeavored to test natural philosophy, thereby building a bridge between it and factual research. His scientific integrity kept him always nearer to the facts than to lofty "speculations." He likened himself to a "thinking anatomist or physiologist" who investigates the structure of the earth organism, critically recording and evaluating all facts in the hope of discovering the underlying plan ("no matter whether it be divine or natural"). He did not conceal facts, nor did he abuse them; but he did expect that after a mass of detail was digested he would find a system that would not only permit an interpretation of the earth in mechanical terms but would also be meaningful.

Ritter was much more critical and cautious than many of today's scholars, who are inclined to generalize and to establish rules and laws. His belief in a world order (divine or natural) never led him to a distortion or misrepresentation of facts, and it served him as an incentive for finding innumerable connections which before him the "meaningless description of the earth could not have imagined." Thus he sought to justify himself vis-à-vis the kind of science that developed around him, which considered it its first duty to divest the world of myth; and he provoked the accusation that he was a teleologist, which has dimmed his reputation as a scientist to the present day.

#### RITUAL

Citations in the *Oxford English Dictionary* from the fourteenth century on reveal two distinct trends of common usage for the words *rite* (*ritual*), *ceremony* (*ceremonial*), and *custom* (*customary*). On the one hand, these terms have been used interchangeably to denote any noninstinctive pre-

dictable action or series of actions that cannot be justified by a "rational" means-to-ends type of explanation. In this sense the English custom of shaking hands is a ritual, but the act of planting potatoes with a view to a harvest is not. But rationality is not easily defined. A psychiatrist may refer to the repeated hand washing of a compulsive neurotic as a "private ritual" even when, in the actor's judgment, the washing is a rational means to cleanliness. Likewise, a high-caste Hindu is required by his religion to engage in elaborate washing procedures to ensure his personal purity and cleanliness; the rationality or otherwise of such actions is a matter of cultural viewpoint. In this case, anthropologists who distinguish between ritual cleanliness and actual cleanliness are separating two aspects of a single state rather than two separate states. The distinction between cleanliness and dirt is itself a cultural derivation that presupposes an elaborate hierarchy of ritual values. If "nonrationality" is made a criterion of *ritual*, it must be remembered that the judge of what is rational is the observer, not the actor.

The other trend of usage has been to distinguish the three categories: ritual, ceremony, and custom. Ritual is then usually set apart as a body of custom specifically associated with religious performance, while ceremony and custom become residual categories for the description of secular activity. Where religion is the specific concern of fully institutionalized churches, as in Europe, a religious delimitation of ritual is unambiguous and easy to apply; in the exotic societies studied by anthropologists this is not the case. Recognizing this problem, some contemporary authors have argued that ambiguity in the data may be overcome by the multiplication of analytic concepts (e.g., Firth 1956, p. 46; Wilson 1954, p. 240; Gluckman 1962, pp. 20-24). Gluckman, in particular, favors an elaborate vocabulary giving clearly distinguishable meanings to *ceremony*, *ceremonious*, *ritual*, *ritualism*, and *ritualization*, but the circumstances in which precision might be useful are hard to imagine. Ritual is clearly not a fact of nature but a concept, and definitions of concepts should be operational; the merits of any particular formula will depend upon how the concept is being used.

In short, to understand the word *ritual* we must take note of the user's background and prejudices. A clergyman would probably assume that all ritual necessarily takes place inside a church in accordance with formally established rules and rubrics; a psychiatrist may be referring to the private compulsions of individual patients; an anthropologist will probably mean "a category of standardized

behavior (custom) in which the relationship between the means and the end is not 'intrinsic'" (Goody 1961, p. 159), but he will interpret this definition loosely or very precisely according to individual temperament. The associated terms *ceremonial* and *customary* are also used in very varied ways, even by professionals from the same discipline.

### Historical usage of the concept

The views of Robertson Smith (1889) are of particular relevance in arriving at a definition of terms. As a former professor of divinity, he advocated the study of comparative religion. He assumed that the boundaries between what is religion and what is not religion are self-evident. Modern religion (Christianity) consists of beliefs (dogma) and practices (ritual); "in the antique religions mythology takes the place of dogma." Myth is merely "an explanation of a religious usage." Hence, "the study of ancient religion must begin, not with myth, but with ritual and traditional usage." The thesis that religion consists essentially of beliefs and rituals and that, of the two, ritual is in some sense prior has influenced many later writers in many different fields.

Durkheim ([1912] 1954, p. 47) defined religion as "a unified system of beliefs and practices (rites) relative to sacred things, that is to say, things set apart and forbidden—beliefs and practices which unite into a single moral community called a Church, all those who adhere to them." Rites, for Durkheim, are "the rules of conduct which prescribe how a man should comport himself in the presence of these sacred objects" (*ibid.*, p. 41). Negative (ascetic) rites are the customs that we commonly label *taboo*. Positive rites include "imitative rites," which are in fact the same practices that Frazer called "homeopathic magic"; "representative or commemorative rites," which are the cults of ancestor worship; sacrifice; and placular rites, or memorials to misfortune, such as mourning. The overprecision of Durkheim's classification leads to some difficulties. He asserts dogmatically that "the division of the world into two domains, the one containing all that is sacred, the other all that is profane, is the distinctive trait of religious thought" (*ibid.*, p. 37). In his system, magic belongs to the sphere of the profane, even though "magic, too, is made up of beliefs and rites" (*ibid.*, p. 42).

The same set of rituals may readily be classified in other ways. Thus van Gennep (1908) proposed a category to cover all individual life-crisis ceremonials (e.g., those associated with birth, puberty,

marriage, death) and also recurrent calendric ceremonies such as birthdays and New Year's Day. He called these "rites of passage." In practice, van Gennep's schema has proved more useful than Durkheim's (see Gluckman 1962).

If Durkheim seems to be excessively rigid, Frazer, who was Robertson Smith's pupil, errs in the opposite direction. In the pages of *The Golden Bough* (1890) the words *custom*, *ceremonial*, *rite*, and *ritual* seem to be interchangeable. Belief and rite are assumed to be so closely interdependent that if evidence concerning either is available the author may confidently "conjecture" as to the other, which he does very freely. Employing similar assumptions, later writers have felt entitled to make the most sweeping reconstructions of ancient religious systems on the basis of slender archeological residues of ritual practice (Hooke 1958).

A more profitable development of Robertson Smith's theme was the inquiry by Jane Harrison (1912; 1913) into the relationship between ritual and art. Harrison noted that the Greek word *drama* is derived from *dromenon* (religious ritual, literally: "things done"). She attached special importance to Durkheim's category of "imitative rites": "Primitive man . . . tends to re-enact whatever makes him feel strongly; any one of his manifold occupations, hunting, fighting, later ploughing and sowing, provided it be of sufficient interest and importance, is material for a *dromenon* or rite." ([1913] 1951, p. 49). Thus ritual is seen as a magical dramatization of ordinary activities, while in turn the drama is a secular recapitulation of ritual. Although ritual is distinguished from non-ritual by the presence or absence of a religious context, the details of this distinction remain imprecise.

Harrison was a classical scholar who profited from the writings of anthropologists; the succeeding generation of anthropologists in turn profited from hers. Malinowski and Radcliffe-Brown introduced the concept of functionalism into British social anthropology; they were both indebted to Harrison, though both were also, and quite independently, the propagators of Durkheim's ideas. The concept of "ritual value," which Radcliffe-Brown developed in *The Andaman Islanders* (1922) and later writings, is essentially that espoused by Harrison. Objects to which ritual value attaches are objects that are socially important for secular reasons. Radcliffe-Brown, however, added the proposition that the performance of ritual generates in the actors certain "sentiments" that are advantageous to the society as a whole. In their discussions of this theme both Radcliffe-Brown and

Malinowski tend to assume that economic value depends upon utility rather than scarcity, and they attempt to distinguish ritual value as something other than economic value. Radcliffe-Brown shows that the Andamanese attached "ritual value" to objects (including foods) that were scarce luxuries, but he makes an unnecessary mystery of this fact. Karl Marx had a much clearer understanding of what is, after all, our common experience. Marx observed that the value of commodities in the market is quite different from the value of the same goods considered as objects of utility. He distinguishes the extra value that goods acquire by becoming market commodities as "fetichistic value" (1867-1879). This concept is closely akin to Radcliffe-Brown's "ritual value," though in Marx's argument the magical element is only an aspect of the commodity value, rather than the value as a whole. Furthermore, where Radcliffe-Brown urged that ritual is to the advantage of society, Marx claimed that it is to the disadvantage of the individual producer. The Marxist thesis is that in the activities of the secular market—where all values are supposed to be measured by the strictest canons of rationality—judgments are in fact influenced by mystical nonrational criteria. A full generation later Mauss (1925), developing his general theory of gift exchange from an entirely different viewpoint, reached an identical conclusion. Exchanges that appear to be grounded in secular, rational, utilitarian needs turn out to be compulsory acts of a ritual kind in which the objects exchanged are the vehicles of mystical power.

Of the authors I have mentioned, Durkheim, Harrison, Radcliffe-Brown, and Mauss all started out with the assumption that every social action belongs unambiguously to one or the other of two readily distinguishable categories: the nonrational, mystical, nonutilitarian, and sacred or the rational, common-sense, utilitarian, and profane. Each author would clearly like to distinguish a specific category, *ritual*, which could refer unambiguously and exhaustively to behavior relevant to things sacred. Each author ends up by demonstrating that no such discrimination is possible—that all "sacred things" are also, under certain conditions, "profane things," and vice versa. Malinowski sought to avoid this dilemma. For him, the essential issue was that of rationality rather than religion. Those who followed Frazer in thinking of magic as "a false scientific technique" necessarily classed magic as a profane activity, but according to Malinowski, primitive man has a clear understanding of the difference between a technical act

and a magical rite. Magic and religion both belong to a single sphere, the magico-religious; "... every ritual performance, from a piece of primitive Australian magic to a Corpus Christi procession, from an initiation ceremony to the Holy Mass, is a traditionally enacted miracle. . . . Man needs miracles not because he is benighted through primitive stupidity, [or] through the trickery of a priesthood . . . but because he realises at every stage of his development that the powers of his body and of his mind are limited" ([1923-1939] 1963, pp. 300-301).

But if ethnography offers little support to Durkheim, it offers still less to Malinowski. Most people in most societies have only the haziest ideas about the distinction either between sacred and profane or between rational and nonrational; it is a scholastic illusion to suppose that human actions are everywhere ordered to accord with such discriminations. Some authors still hold that a specific category is delimited by the phrase "behavior accounted for by mystical action": in my view they are mistaken.

### Ritual and communication

In this whole discussion two elements are involved which have so far been scarcely mentioned. Human actions can serve to *do* things, that is, alter the physical state of the world (as in lighting a bonfire), or they can serve to *say* things. Thus, the Englishman's handshake makes a complicated statement such as, "I am pleased to meet you and willing to converse." All speech is a form of customary behavior, but, likewise, all customary behavior is a form of speech, a mode of communicating information. In our dress, in our manners, even in our most trivial gestures we are constantly "making statements" that others can understand. For the most part these statements refer to human relationships and to status.

The actions that "say things" in this way are not as a rule intrinsically different from those that "do things." If I am cold, I am likely to put on more clothes, and this is a rational action to alter the state of the world; but the kinds of clothes I put on and the way I wear them will serve to "say things" about myself. Almost every human action that takes place in culturally defined surroundings is divisible in this way; it has a technical aspect which does something and an aesthetic, communicative aspect which says something.

In those types of behavior that are labeled ritual by any of the definitions so far discussed, the aesthetic, communicative aspect is particularly prominent, but a technical aspect is never entirely

absent. The devout Christian eats and drinks as part of a sacrament, but he also says grace as a preface to an ordinary meal. These are plainly "ritual" matters. But it is equally a matter of "ritual" that whereas an Englishman would ordinarily eat with a knife and fork, a Chinese would use chopsticks, and an Indian his right hand (but not his left, which for complex reasons is deemed polluted).

**The meaning of ritual.** Whether we use a narrow or a broad definition of ritual, one major problem is that of interpretation. What does ritual mean? If a ritual act be deemed to say something, how do we discover what it says? Clearly the actor's own view is inadequate. With minor variations the ritual of the Christian Mass is the same throughout Christendom, but each individual Christian will explain the performance by reference to his own sectarian doctrine. Such doctrines vary quite widely; the social scientist who seeks to understand why a particular ritual sequence possesses the content and form that he observes can expect little help from the rationalizations of the devout. But intuition is equally unreliable. Sacrifice, in the sense of the ritual killing of an animal victim, is an institution with a world-wide distribution. How can we explain this? Why should this particular kind of rite be considered an appropriate kind of action in the situations in which it is observed? There is no lack of theory. Some argue that the victim is identified with God and then sacramentally eaten; others that the victim is a gift or a bribe to the gods; others that the victim stands in substitution for the giver of the sacrifice; others that the victim is a symbolic representation of sin; and so on. All these explanations may be true or partly true for particular situations, but they cannot all be true at once, and none of them reach into the heart of the problem, which is, Why should the killing of an animal be endowed with sacramental quality at all?

Some interpretative approaches are more clearly formulated than others and deserve special attention. Radcliffe-Brown (1922) postulated that human beings always manipulate their thought categories consistently. We can discover what a ritual symbol means by observing the diverse uses of that symbol in both ritual and secular contexts. This is a powerful but by no means foolproof interpretative device. For example, the English speak of "high" status versus "low" status. We might then suppose that in ritual drama the person who is "higher" will always be superior. Up to a point this applies. Persons of authority are raised on a dais;

a suppliant kneels; an orator stands when his audience sits. But there are also situations where persons of extreme eminence sit (e.g., a king on his throne) when all others stand. The regularities are not simple.

This should not surprise us. In seeking to understand ritual we are, in effect, trying to discover the rules of grammar and syntax of an unknown language, and this is bound to be a very complicated business.

Lévi-Strauss (1962) is inclined to see ritual procedures as integral with processes of thought. The drama of ritual breaks up the continuum of visual experience into sets of categories with distinguishable names and thereby provides us with a conceptual apparatus for intellectual operations at an abstract and metaphysical level. Such an approach implies that we should think of ritual as a language in a quite literal sense. Various theorems of communication engineering and of structural linguistics should thus be applicable. We can, for example, start to investigate the role played by "redundancy" in ritual. Do binary contrasts in ritual correspond to phonemic contrasts in verbal speech forms? Can we discover, in any particular culture, rules concerning the development of a ritual sequence that would be comparable to the rules of generative grammar which Chomsky (1957) suggests must govern the modes by which each individual composes a verbal utterance? This is a field in which exploration has hardly begun.

**Ritual as social communication.** Most modern anthropologists would agree that culturally defined sets of behaviors can function as a language, but not all will accept my view that the term *ritual* is best used to denote this communicative aspect of behavior. Although we are still very much in the dark as to how ritual behaviors manage to convey messages, we understand roughly what the messages are about and at least part of what they say. Social anthropologists and sociologists alike claim that their special field is the study of systems of social relationship. This notion of social relationship is a verbal derivation based on inference. We do not observe relationships; we observe individuals behaving toward one another in customary, ritually standardized ways, and whatever we have to say about social relationships is, in the last analysis, an interpretation of these "ritual" acts. All of us in our private daily lives manipulate the symbols of an intricate behavioral code, and we readily decode the behavioral messages of our associates; this we take for granted. Comparable activities on a collective scale in the context of a religious institution are rated mysterious and irra-

tional. Yet their functional utility seems plain enough. Our day-to-day relationships depend upon a mutual knowledge and mutual acceptance of the fact that at any particular time any two individuals occupy different positions in a highly complex network of status relationships; ritual serves to reaffirm what these status differences are. It is characteristic of all kinds of ritual occasion that all participants adopt special forms of dress, which emphasize in an exaggerated way the formal social distinctions that separate one individual from another. Thus, ritual serves to remind the congregation just where each member stands in relation to every other and in relation to a larger system. It is necessary for our day-to-day affairs that we should have these occasional reminders, but it is also reassuring. It is this reassurance perhaps that explains why, in the absence of scientific medicine, ritual forms of therapy are often strikingly successful.

Here the argument seems to have come full circle. For if ritual be that aspect of customary behavior that "says things" rather than "does things" (cf. Parsons' instrumental-expressive dichotomy), how is it that, in the view of the actors (and even of some analysts), ritual may "do things" as well as "say things." The most obvious examples are healing rituals which form a vast class and have a world-wide distribution, but here we may also consider role-inversion rituals, which Gluckman (1962) has classed as "rituals of rebellion" and which he perceives as fulfilling a positive cathartic function.

**Ritual as power.** From the viewpoint of the actor, rites can alter the state of the world because they invoke power. If the power is treated as inherent in the rite itself, the analyst calls the action magic; if the power is believed to be external to the situation—a supernatural agency—the analyst says it is religious. Current argument on this theme is highly contentious, and I must declare my own position: I hold that the rite is prior to the explanatory belief. This will be recognized as essentially the view of Robertson Smith.

The concept of power itself is a derivation. We observe as an empirical fact that an individual *A* asserts dominance over another individual *B*; we observe that *B* submits to *A*, and we say that "A has power over B." And then in a ritual context we observe another individual *A'* going through a performance that he believes will coerce a fourth individual *B'*; or alternatively, we observe *B'* making a ritual act of submission to an unseen presence *C'*. The normal classification declares that the acts of *A* and *B* are rational but that the acts

of  $A^1$  and  $B^1$  are irrational. To me it seems that they are all actions of the same kind. The "authority" by which  $A$  is able to coerce and control the behavior of  $B$  in a secular situation is just as abstract and metaphysical as the magical power by which  $A^1$  seeks to coerce  $B^1$  or the religious power that  $B^1$  seeks to draw from  $C^1$ . Ideas about the relations between supernatural agencies and human beings or about the potency of particular ritual behaviors are modeled on first-hand experience of real-life relationships between real human beings. But conversely, every act by which one individual asserts his authority to curb or alter the behavior of another individual is an invocation of metaphysical force. The submissive response is an ideological reaction, and it is no more surprising that individuals should be influenced by magical performances or religious imprecations than that they should be influenced by the commands of authority. The power of ritual is just as actual as the power of command.

**Ritual as belief.** Unlike Robertson Smith, Tylor (1871) assumed the priority of belief over ritual. In England a Neo-Tylorian view has a number of contemporary advocates. According to their argument, it is the belief accompanying the behavior, rather than any quality of the behavior itself, that distinguishes ritual. Since the participants in a religious ritual claim that their actions are designed to alter the state of the world by bringing coercive influence upon supernatural agencies, why should we not accept this statement at its face value? Why invoke the proposition that the actions in question are, as Durkheim would have it, "symbolic representations of social relationships." Goody counterposes the intellectualized interpretation of social behavior made by the observer to the statement of the actor himself. "What happens, then," writes Goody (1961, p. 157), "is that symbolic acts are defined in opposition to rational acts and constitute a residual category to which 'meaning' is assigned by the observer in order to make sense of [the] otherwise irrational. . . ." Ritual acts are to be interpreted in the context of belief: they mean what the actors say they mean. This common-sense approach clearly has its attractions. Yet it may be argued that if culturally-defined behavior can only be interpreted by the actors, all cross-cultural generalization is impossible, and all attempts to make a rational analysis of the irrational must necessarily be fallacious (see Goody 1961, p. 155). In contrast, I, along with other Durkheimians, continue to insist that religious behavior cannot be based upon an illusion.

Jane Harrison's thesis that "ritual is a dramatisation of myth" was reformulated by Malinowski in the assertion that "myth is a charter for social action." According to this argument, myth and ritual are not merely interdependent; they jointly provide a model for "correct" moral attitudes in secular life. But although it is easy to cite examples in which rituals enshrine in a quite straightforward way the most strongly felt values of society, there are many striking exceptions. The characters of myth frequently break all the moral conventions of mundane society in the most glaring way, and in many rituals the actors are required to behave in a manner precisely contrary to that which they would be expected to adopt in ordinary life. Two very different types of explanation have been offered for facts of this kind. One sees this role inversion as symbolic; the events of myth and ritual refer to the space-time of "the other world"; they belong to Durkheim's category of the *sacred*, and to express this fact their content systematically inverts whatever is appropriate to "this world," the *profane*. In contrast, Gluckman, in an argument that has wide application (see Norbeck 1961, pp. 205-211), stresses the aggressive elements present in role-reversal ceremonies, which he aptly names "rituals of rebellion" (Gluckman 1962). The performers, he suggests, act out in dramatic form hostilities that are deeply felt but may not be expressed in normal secular relationships. This acted aggression serves as a cathartic release mechanism, and by relieving tension these inverted behaviors actually serve to strengthen the moral code they appear to deny. It is an ingenious argument but hard to validate. Once again we are faced with the difficulty that sharply contrasted interpretations seem to afford partial explanations of the same ethnographic facts, so that choice of theory becomes a matter of personal predilection.

Nineteenth-century positivist thinkers made a triadic distinction between reason, magic, and religion. Various authors have attempted to fit ritual to this triad and also to the two dichotomies: sacred-profane, rational-nonrational. Some of the resulting difficulties have been considered. It is argued that no useful distinction may be made between ritual acts and customary acts but that in discussing ritual we are concerned with aspects of behavior that are expressive (aesthetic) rather than instrumental (technical). Ritual action, thus conceived, serves to express the status of the actor vis-à-vis his environment, both physical and social; it may also serve to alter the status of the actor.

When ritual functions in this latter sense, it is a manifestation of power; thus, the universal belief in the potency of ritual action is by no means an illusion. No attempt has been made to discuss the forms of ritual. Any form of secular activity, whether practical or recreational, can be stylized into dramatic performance and made the focus of a ritual sequence. Such stylization tends to distort the secular norm in either of two directions: the emphasis may be ascetic, representing the intensification of formal restraint, or ecstatic, signifying the elimination of restraint. Ascetic and ecstatic elements are present in most ceremonial sequences, and the contrast may form part of the communication code (Leach 1961, chapter 6). Finally, it has been stressed that even among those who have specialized in this field there is the widest possible disagreement as to how the word ritual should be used and how the performance of ritual should be understood.

#### RIVERS, W. H. R.

William Halse Rivers (1864-1922), British anthropologist and medical psychologist, was educated at Tonbridge School and St. Bartholomew's Hospital, London. He held a medical degree, was elected a fellow of the Royal College of Physicians, and was a lecturer in experimental psychology at Guy's Hospital, London. From 1897 on, he was a lecturer at Cambridge University and was responsible for founding the Cambridge school of experimental psychology. He became a fellow of St. John's College, Cambridge, in 1902. In 1898 he joined the Cambridge anthropological expedition to Torres Strait led by A. C. Haddon and was in charge of the psychological work. He made several ethnological investigations: of the Todas in south India in 1902, and in Melanesia, in 1908 and again in 1914. During World War I Rivers performed distinguished service as a psychopathologist working in military hospitals. He was one of the few English medical men of that period to recognize the far-reaching significance of the work of Freud; he himself made important contributions to the study of war neurosis. He received honorary

degrees from the universities of St. Andrews and Manchester and was a fellow of the Royal Society. He was president of the Folklore Society in 1920–1921 and president of the Royal Anthropological Institute in 1921–1922. His death following an operation was unexpected; he was only 58 and actively engaged in many intellectual activities.

**Anthropological career.** Rivers' lifelong interest in the twin disciplines of medical psychology and anthropology had long antecedents. His father, the Reverend H. F. Rivers, had studied under his own brother-in-law, James Hunt, the owner of a fashionable (and very profitable) institute of speech therapy, which had been founded by Hunt's father early in the century. On Hunt's death in 1869, H. F. Rivers took over the institute and brought out a revised edition of Hunt's book, *Stammering and Stuttering: Their Nature and Treatment*. But Hunt, besides being a practical exponent of experimental psychology, had been very prominent in the early history of British anthropology. He had been honorary secretary of the Ethnological Society of London from 1859 to 1862 and then founded and financed a breakaway institution called the Anthropological Society of London, which survived as a separate entity until 1871. The present Royal Anthropological Institute, of which Rivers was president at the time of his death, is a successor institution to the two parent bodies with which his maternal uncle had been associated at the time of Rivers' birth.

Rivers' professional status was that of a psychologist, but he is principally remembered for his contributions to anthropology. On the Torres Strait expedition of 1898 he developed a keen interest in ethnographic problems, particularly in the algebraic peculiarities of kin-term systems. He devised a "genealogical method" for recording the mutual kinship connections of the members of a closed community, a method that proved to be of lasting importance (Rivers 1900). Rivers brought to his anthropological studies a scientific detachment and experimental rigor wholly different from the spirit of classical scholarship that pervades the writings of his celebrated Cambridge colleague Sir James Frazer. It is primarily because of Rivers that most British social anthropologists now think of themselves as being engaged in a science rather than a literary exercise. By the standards of its time *The Todas* (1906) was an outstanding example of precise documentation, and for many years this book served British anthropologists as a model for ethnographic monographs.

Like all his contemporaries, Rivers took it for granted that the objective of the anthropologist is

to reconstruct the history of the primitive peoples whom he studies. During the early part of his career Rivers' historical assumptions were those of an evolutionist. In this respect he was a follower of L. H. Morgan, whose studies of kinship terminologies (Morgan 1871) had been largely neglected in England. The functionalist reaction against evolutionism, under the twin but discordant trumpets of B. Malinowski and A. R. Radcliffe-Brown, did not achieve general acceptance until some years after Rivers' death. Even so, Radcliffe-Brown, who made his expedition to the Andaman Islands in 1906 under the tutelage of Haddon and Rivers, retained throughout his career a strong interest in the problems of kinship terminology that had so obsessed Rivers. Although this interest led Rivers into many fanciful excesses of "kinship algebra," whereby he deduced sociological conditions that can certainly never have existed, it was a bias which proved to be a crucial step in the development of the "structuralist" orientation of contemporary British social anthropology (which derives from Rivers by way of Radcliffe-Brown) as distinct from the "cultural" orientation which dominated the work of Tylor, Frazer, and Malinowski.

Around 1910 Rivers developed a close friendship with Sir Grafton Elliot Smith, a medical colleague who advocated an extreme diffusionist doctrine, claiming that the whole of human civilization was derived from that of ancient Egypt [see DIFFUSION, article on CULTURAL DIFFUSION]. Rivers' uncritical acceptance of Smith's dogmatic and wildly exaggerated assertions is a matter for astonishment. Nearly all of Rivers' later anthropological writings, including the very important *History of Melanesian Society* (1914a) and *Kinship and Social Organization* (1914b), show Smith's influence to a marked degree, usually to their detriment. Rivers' anthropological textbook, *Social Organization* (1924b), although it was mutilated by its editors, Elliot Smith and W. G. Perry, and was certainly not in the same class as R. H. Lowie's *Primitive Society* (1920), still merits serious attention.

Rivers' discrimination of concepts has a scientific clarity that is commonly lacking in anthropological writing. Although the problems of *descent*, *succession*, and *inheritance* are not so simple as Rivers supposed, he at least perceived the nature of problems that many later writers have ignored. Among his earlier works the ethnographic accounts of the Todas (1906) and of the Banks Islanders (1914a, vol. 1) have permanent merit, but the high esteem formerly placed upon his theoretical studies of kinship terminologies now seems misplaced. In studying kin terms, Rivers, like Morgan,

assumed that classificatory usages must be "survivals" of an earlier state of society. Rivers' most astonishing historical reconstruction of this kind occurs in *Kinship and Social Organisation* (1914b, pp. 33-38), where he invented a social system that required a man to marry either his mother's brother's wife or his brother's daughter's daughter. The reconstructions of history found in more modern work, such as Murdock's *Social Structure* (1949), lack the preposterous quality which marks many of Rivers' examples, but they rest upon assumptions concerning the nature of kinship that are basically very similar.

In sum, very little of Rivers' "kinship theory" can still be taken seriously, but its influence can still be traced. In England, Radcliffe-Brown, Brenda Seligman, J. Layard, and A. M. Hocart all produced work in this field which derived from that of Rivers and which has had a lasting influence upon the thinking of British social anthropologists, even though the latter no longer concern themselves with historical reconstructions. Oddly enough, although Rivers' influence in the United States is very indirect, there are some contemporary American writers, such as Robert and Barbara Lane, who stand very close indeed to Rivers' way of thinking. Rivers' influence on his psychological successors was much less pronounced, though some early work by his friend F. C. Bartlett, who was later professor of experimental psychology at Cambridge, perpetuates Rivers' ideas (e.g., Bartlett 1923).

#### RIVET, PAUL

Paul Rivet, French ethnologist and Americanist, was born at Wassigny, in the Ardennes, in 1876 and died in Paris in 1958. He studied medicine at the Faculty of Medicine and the École du Service de Santé Militaire of Lyons, where he obtained the degree of doctor of medicine in 1898. In 1901 he was attached to the scientific mission of General Bourgeois, which was sent to Ecuador to verify certain terrestrial measurements made at the end of the eighteenth century by Pierre Bouguer, Louis Godin, and Charles Marie de La Condamine. After the mission returned, Rivet stayed on for six years, studying the populations of the high valleys of the Andes. From that time on, he devoted himself to anthropological and linguistic researches.

When Rivet returned to France, the Musée National d'Histoire Naturelle engaged him to classify and study the collections of anthropological and linguistic documents that he brought back (1912-1922). He became an assistant to René Verneau, who held the chair of anthropology at the museum, and then assistant director of the laboratory, a post he held until he was himself appointed to the chair of anthropology in 1928. The focus of his interest was the geology, geography, and linguistics of the Americas. He organized weekly meetings at his home, at which both French and foreign scientists presented and discussed the results of their work on the Americas; these meetings continued for fifty years, interrupted only by two world wars.

In 1926 Rivet took part in creating the Institut d'Ethnologie of the University of Paris, where he

helped to train a great many French and foreign ethnologists. He took over the chair of anthropology of the Musée National d'Histoire Naturelle in 1928 and later succeeded in having one wing of the new Palais de Chaillot allotted to an ethnographical museum, eventually transforming this museum into the great Musée de l'Homme, famous for its fossil-man collections. In 1942 he was welcomed to Colombia by President Eduardo Santos and there founded the Colombian Institute of Ethnology and set up a Musée de l'Homme in Bogotá that was modeled on the one in Paris. After a period in Mexico as cultural delegate of Free France, Rivet resumed, in 1945, his chairs at the museum and the Institut d'Ethnologie, as well as the directorship of the Musée de l'Homme. He also continued his research in South America and sparked the activities of the Société des Américanistes in Paris.

The basic concept of Rivet's extensive work is the notion that there is "a real interdependence, however hard it may sometimes be to prove it, among linguistics, ethnology, and [physical] anthropology" (1927, p. 14). In tracing the origins of American aboriginals, therefore, he compared anthropometric studies of fossils with those made on living peoples; he also studied distributions of cultural elements, such as language, religion, music, games, weapons, household furnishings, and tools, as well as of blood groups and pathologies. Combining these studies with the results of research done by others, he developed his central thesis—that the peopling of America did not derive exclusively from Asia. In opposition to Hrdlička's theory that the population of America came only from Asia, via the Bering Strait, the Aleutians, and the northwest, a theory that at that time still had considerable support, Rivet believed that two other sources also contributed to the peopling of South America. He did not deny that the major part of the population had come from Asia but insisted that there had been migrations (1) from Australia, dating back at least six thousand years, and (2) from Melanesia, at a later but still ancient period. The migration from Australia must have followed the shores of the Antarctic, making use of the chains of islands that bind that continent to Australia on the one hand and to America on the other ([1943] 1957, p. 24; 1956). The Melanesian migration, he believed, took place in a succession of waves, by the maritime route of the South Pacific. In his publications on this subject, Rivet presented not only the anthropological, linguistic, and other evidence for his theory about these migrations but also described the similarities between the primi-

tive populations of South America and Oceania that initially led him to formulate it.

In his linguistic work he pointed out many relationships of a fairly narrow scope, almost always with great reliability. His contribution in providing considerable data on otherwise unknown languages was also considerable.

RAYMOND RONZE

#### ROBERTSON, DENNIS HOLME

Sir Dennis Holme Robertson was born at Lowestoft, England, in 1890 and died at Cambridge in 1963. He made his most important contribution to economics in the fields of monetary theory and industrial fluctuation, but his range was wide, and his writings cover many aspects of economics and the economic and social problems of his time. Like many of his predecessors and contemporaries, he came to economics from another discipline. In 1908 he entered Trinity College, Cambridge, with

a major scholarship in classics, and two years later he was placed in the first division of the first class of the classical tripos and won the Craven scholarship. In three successive years he also won the chancellor's medal for English verse, and he continued to write poetry for most of his life. He had a superb mastery of the language, and his writing is well known for its clarity, conciseness, and elegance. In 1910 he abandoned classics for economics. At this time economics at Cambridge was dominated by the work of Alfred Marshall, which remained the principal influence on Robertson. Robertson became a pupil of J. M. Keynes (his senior by seven years), thus beginning a collaboration that was to last for more than twenty years. He obtained a first class in the economics tripos in 1912 and turned to his first piece of research, which was completed early in 1914 and published in 1915 as *A Study of Industrial Fluctuation*.

**Work on the trade cycle.** *A Study of Industrial Fluctuation* is a remarkable work for so young an economist. Robertson collected a mass of empirical data, and although some of his methods appear amateurish by later standards (he was working singlehandedly and without any statistical aids), he derived conclusions of great importance. In particular, he stressed the role of invention and innovation in determining the course of investment and therefore of general economic activity, thus helping to explain the causation and mechanics of the trade cycle. This new approach also implied that fluctuations are closely associated with economic progress and are to some extent part of the price to be paid for it—a conclusion which is not always now accepted but which Robertson continued to hold. This is not to say that he considered that countercyclical policy need be totally ineffective: this early work contains suggestions which were well in advance of their time, such as “a somewhat saner and more centralized investment policy” ([1915] 1948, p. 246) and an attack on what in the 1930s became known as the “Treasury view” of the ineffectiveness of public expenditure as a means of combating depressions.

Apart from its particular conclusions, three features of the book were to remain characteristic of all his later work. First, there is very little in it about “monetary” problems as such. In a new introduction to the 1948 reprint, he stated that he had “been taught to be constantly trying to dig down below the money surface of things” (p. xii), and even in his later work in monetary theory he constantly turned to the influence of “real” forces. Thus, for example, he continued to emphasize the importance of the classical forces of productivity

and thrift as factors determining the rate of interest, unlike economists who regarded it as a purely “monetary” phenomenon determined in the market for bonds. Second, there is an awareness of the complexity of the phenomenon of fluctuation and of all economic phenomena, which left him “with an abiding sense of the difficulty of providing . . . neat little models of the trade cycle and (*a fortiori*) neat little packets of therapeutic pills” (p. x). Third, there is emphasis on structural problems. Although the theme is fluctuation in real income as a whole (in itself a new emphasis, which was rediscovered by some writers in the 1930s), the treatment is permeated by recognition of the effects of changes in one sector of the economy, or in one industry, on the other sectors and industries, and therefore on the aggregate.

**Early work on monetary theory.** When *A Study of Industrial Fluctuation* was published in 1915, Robertson was in the army. He had joined up on the first day of World War I and served throughout, mainly in Egypt and Palestine, as a transport officer. After the war he returned to Cambridge, where he stayed until 1938. It was during this period that he turned to intensive work in monetary theory, at first in close collaboration with Keynes but later as one of his foremost critics. His contributions are contained mainly in two small books, *Money*, published in 1922 (with revised editions in 1924 and 1928 and many subsequent reprints), and *Banking Policy and the Price Level*, published in 1926. The former is a general textbook in a series edited by Keynes, but it is also an important contribution to the development of ideas. Robertson's aim was to “try to re-integrate the theory of money into that of the trade cycle” ([1915] 1948, p. xv). The period in which he wrote was one of monetary instability; the inflation of the war and postwar years was followed by collapse. Traditional financial policies were inadequate to deal with instability and even partly contributed to it, and the mechanisms involved were very imperfectly understood. Virtually the only theory was a rather crude form of quantity theory, which attributed rising prices to the effects of increasing note issue. Robertson's main innovation (and it was fundamental) was to shift the emphasis from the issue of notes to the creation of bank credit and then to break down the process of inflation into a sequence of stages; he also considered the reverse process of deflation (this was in 1922 when the fall in prices had started), giving a warning against too precipitate a return to the gold standard. This analysis was developed in *Banking Policy and the Price Level*, as well as in the later

editions of *Money*, its central theme being the key importance of saving and investment as the determinants of the level of economic activity, with the banking system as the means whereby savings are translated (or not translated) into investment. The step-by-step method of analysis is carried further here than in the earlier work. The implications for policy were the same as those he explicitly stated later: "... the ideal banking policy might be one which was founded on the principle of price-stabilisation as a norm, but which was ready to see the fruits of a prolonged and general increase in individual productivity shared in the form of lower prices, and perhaps to acquiesce in moderate price-rises in order that advantage might be taken of discontinuous leaps in industrial technique" ("Theories of Banking Policy" in [1924-1940] 1956, p. 59). He consistently maintained this view; it is found, for example, in his last work, *Memorandum Submitted to the Canadian Royal Commission on Banking and Finance* (1963).

**Problems of industrialism.** In 1923, immediately after writing *Money*, Robertson published *The Control of Industry*, another volume in the series of textbooks edited by Keynes. The theme is the problem of "how, if at all, [we can] ensure that the men and women engaged in industry shall not become mere instruments of production or mere passive receptacles of its fruits, but shall retain, in their relation to the economic circumstances of their life, the character of self-directing human beings?" ([1923] 1960, pp. 1-2).

It was characteristic of Robertson not to offer easy solutions but rather to present a penetrating and balanced discussion of the nature of the problems to be solved. The scope of the book is, indeed, wider than this theme would suggest, for in its short compass it is no less than a critique of the underlying principles and typical organizations of modern capitalism. He identified the following tenet as the main principle of free enterprise: "Where the risk lies, there the control lies also." He explored its application to a wide range of proposals and attempts to change the methods of control of industry, ranging from revolutionary syndicalism to consumers' cooperatives and workers' copartnership. Although he did not claim any originality of thought on the subject, the work was a minor classic and is still widely used.

**Response to Keynes's work.** In the introduction to *Banking Policy and the Price Level*, Robertson stated that his collaboration with Keynes had been so close that "neither of us now knows how much of the ideas . . . is his and how much is mine" ([1926] 1949, p. 5). With the publication of

Keynes's *General Theory of Employment, Interest and Money* in 1936, however, their paths diverged. Robertson's criticisms of the Keynesian system are contained in a series of articles, most of which were later republished in volumes of collected essays (see 1924-1940; 1952; 1956). Many of his criticisms were regarded in some quarters as carping at minutiae of a fundamental revolution in economic thinking that he had failed to understand. To Robertson, however, much of the Keynesian "revolution" was retrogression rather than advance. So far as the main analysis was concerned, Robertson regarded Keynes's treatment of the savings-investment complex in terms of static and stable equilibrium as a step backward, leading to confusion and misunderstanding. Although much of the controversy seems to have been about words, especially the definitions of saving and investment, the issue of whether savings and investment are or are not equal in equilibrium was a fundamental one. Similarly crucial was what was meant by equilibrium: for Keynes it was short-period equilibrium; for Robertson it was equilibrium over time, to be analyzed and understood in detail only by his step-by-step method. Further, Robertson's "equilibrium" also implied (indeed, took for granted) the growth of the economy in terms of measurable real output or income. Keynes, on the other hand, was led to the "stagnation thesis," which Robertson regarded as unwarranted analytically and also as being a generalization from one severe but atypical depression. Moreover, the implications for policy of Keynes's system were unambiguously inflationary and thus a departure from Robertson's ideal of ordered progress and monetary stability.

In retrospect, much of the controversy over the *General Theory* seems to have been unduly labored, in part perhaps as a result of the defects of the book and of the extreme positions taken by some of the participants. The Keynesian system was considerably modified and developed under criticism, not least that of Robertson, and the accepted view on some matters became as much Robertsonian as Keynesian. For example, Robertson was right in pointing out that the equality of savings and investment was treated by many of Keynes's followers both as an identity and as an equality achieved by movement of income to an equilibrium level, and many of his further criticisms flowed from this. The controversy over the determinants of the rate of interest showed that a modified Keynesian "liquidity preference" theory and the Robertsonian "loanable funds" approach could in certain circumstances give much the same results, and some economists regard the Robertsonian formulation as

the more fruitful in interpreting dynamic situations. And although Robertson remained out of sympathy with the Keynesian system, his own views underwent modification as he reconsidered his earlier ideas, many of which had originally been worked out in collaboration with Keynes: for example, his discussions after 1945 of problems of inflation would have been very different had it not been for the *General Theory* and its aftermath.

**Later work.** In 1938 Robertson left Cambridge to take up a professorship at the London School of Economics and at the outbreak of World War II joined the Treasury, where his main concern was with the balance of payments and overseas finance. In 1944 he was one of the team accompanying Keynes to the Bretton Woods conference, and he played an important part in the negotiations leading to the final agreement. At the end of the year he returned to Cambridge to succeed A. C. Pigou in the chair of political economy. In that capacity he lectured on economic principles until his retirement in 1957. His lectures, published in three volumes from 1957 to 1959, were in the main an exposition of the problems of value and distribution (although Volume 3, covering only a dozen lectures given in the short third term at Cambridge, is concerned with money and fluctuations). Almost inevitably he based himself on Marshall, but he had kept up with the flood of literature before and after the war, and the lectures constitute an important statement of the present state of some of the central and traditional problems of economics, with much penetrating comment, presented in his own inimitable style. In these years he also wrote a large number of papers on current problems of domestic and international economic policy, as well as some on more theoretical issues; most of these were collected into published volumes of essays (e.g., 1956; 1957-1959). It was at this time that formal worldwide recognition came; he had received an honorary degree from Harvard University at the tercentenary celebration in 1936 and from the University of Louvain, Belgium, in 1947; then, in quick succession, he was honored by the universities of Durham, Manchester, Sheffield, Amsterdam, London, and Columbia. He was knighted in 1953, in recognition of his standing as an economist rather than as a public servant (he had first received public honors on leaving the Treasury in 1944).

Robertson did take some part in public affairs, although usually with some reluctance and out of a strong sense of duty. In particular, from 1944 to 1946 he was a member of the Royal Commission on Equal Pay, exerting a powerful influence on its report. In 1957-1958 he was a member of

the three-man Council on Prices, Productivity and Incomes set up by the chancellor of the Exchequer "to keep under review changes in prices, productivity and the level of incomes (including wages, salaries and profits) and to report thereon from time to time." He was the only economist member and undertook the task with particular reluctance; he had serious doubts about the whole matter of "incomes policy" with which the council was linked, and he knew that his own ideas, which he would be bound to put forward, would be generally unwelcome in the current climate of political and economic opinion. He proved to be right: the trade unions refused to have anything to do with the council, and its first and principal report, in February 1958, had a mixed reception. Although some commentators regarded it as an important contribution to thinking about the current situation (and it contains a good deal of hard analysis behind its apparent simplicity), it was attacked mostly for the very reasons that Robertson had expected, such as its emphasis on the high level of demand, supported by a plentiful supply of money and the pursuit by governments of "full employment policies," rather than on the wage claims of unions, as the main cause of inflation; certain comments on incomes policy and wage restraint; and a Robertsonian preference for monetary stability and falling prices as a result of increasing productivity, rather than for rising prices as a continuous stimulus to activity. After publication of a second report in August 1958, which brought the statistics up-to-date and suggested further investigations, Robertson resigned. His two colleagues resigned in 1960, and a reconstituted council produced one further report before falling into desuetude.

In 1960 Robertson was invited to give the Marshall lectures at Cambridge and chose as his theme *Growth, Wages, Money* (1961)—a complex of subjects that were highly topical but that also took him back to his first work on industrial fluctuation. In his opening statement, he remarked "... I have sometimes hoped that I could be useful by taking some theme which was really too difficult for me and over which the giants were in conflict ... and giving, for the benefit of those I called my fellow-idiot, my impression of the state of the debate" (p. 4). He not only recorded the state of the debate but made many penetrating comments; he quietly pricked some of the more pretentious bubbles of economic theory and policy, and displayed a salutary skepticism about the value of growth "models," of "neat little models of the trade cycle," and of incomes policy as means of dealing with inflation and of ensuring growth. Although he cast doubt

## ROBINSON, JAMES HARVEY

on many of the economic shibboleths of the time, he would have hoped not to "be debarred from being classed among those who genuinely desire to find means to limit the turbulence, without destroying the vitality, of the 'procreant urge of the world'" ([1915] 1948, p. xvii).

## ROBERTSON SMITH, WILLIAM

See SMITH, WILLIAM ROBERTSON.

James Harvey Robinson (1863-1936), by common consent, did more than any other American historian to develop both academic and popular interest in the historiographical movement called the "New History." The New History had two principal and related characteristics. It repudiated the study of history for its own sake, placing it instead at the service of comprehension of the present and improvement of the future. Rather than concentrating on political and diplomatic events, the New History gave primary attention to social, economic, and intellectual developments.

**Education and influences.** Born of a well-to-do family in Bloomington, Illinois, Robinson had a rather unusual precollege education, his main interests at that stage apparently having been in science, notably biology and astronomy. He entered Harvard in 1883 and received his bachelor's degree in 1887, remaining a year for his master's degree. During this time he started work on what was to be his doctoral thesis, "The Original and Derived Features of the Constitution of the United States." He developed no absorbing enthusiasm for historical studies at Harvard, later stating that the only important intellectual inspiration he received there came from his work with William James in psychology and philosophy. Robinson studied for his doctorate in Germany under Hermann Eduard von Holst at the University of Freiburg. After he finished his doctoral work on the American constitution in 1890, von Holst interested him in German constitutional history, and in 1891 Robinson produced his *German Bundesrath*. These subjects were far removed from his later interests in general European intellectual and social history, but at this period of his life Robinson was really absorbed in constitutional history. However, the main permanent influence coming from his studies in Germany was his mastery of historical research and of the auxiliary sciences on which it depends: epigraphy, paleography, lexicography, and diplomatics.

Few historians have been as much affected by natural science as was Robinson, and it had a strong impact on his attitude toward history. His childhood interest in biology was continued and stimulated by his contacts with E. G. Conklin at the University of Pennsylvania (where he held his first teaching position) and with E. B. Wilson at Columbia (where Robinson taught later), as well as by summers at the marine biology laboratory at Woods Hole, Massachusetts. Robinson declared that he derived his genetic view of historical processes from biology rather than from historiography.

He demanded that history go beyond Leopold von Ranke's injunction to describe *what* happened and that it explain *how* and *why* it happened. Robinson was much impressed with the sensational advances that had recently been made in astronomy, and he believed that the new cosmic perspective had implications far more devastating to the traditional supernaturalism than even the teachings of biological evolution.

Those principally responsible for impressing on Robinson the importance of social and economic factors in historical development were Charles A. Beard, James T. Shotwell, Thorstein Veblen, and R. H. Tawney; Shotwell and Veblen, particularly, were inclined to emphasize the effects of technology and mechanization.

Related to Robinson's special concern with intellectual history was his interest in psychology, which dated from the strong impression that William James had made on him at Harvard. He gained a much more thorough, up-to-date, and technical knowledge of the field as the result of his long and close friendship with E. L. Thorndike at Columbia. In his later years Robinson became much interested in psychoanalysis, especially through his friendship with one of the leading analysts of that time, L. Pierce Clark, author of psychoanalytic studies of Napoleon and Lincoln. During their long friendship John Dewey fueled Robinson's interest in philosophical reflection on the course and meaning of history. Next to his interest in psychology the most potent factor encouraging Robinson's concern with intellectual history was his long, intensive, and appreciative study of the French rationalists.

The first person to have an important and enduring influence on Robinson's conception of history was Simon N. Patten, a welfare economist with a marked interest in the history of institutions, with whom Robinson worked at the University of Pennsylvania. Patten helped convince Robinson that the main value of history is its presentation of the past in a manner that facilitates understanding of the present and thereby permits a more rational approach to improvement of the future. Beard's early socialist inclinations also exerted some influence on Robinson's concern with the meliorative effect of historical knowledge. During his later years at Columbia Dewey's pragmatic philosophy, his leadership in progressive education, and his other strong reformist interests constituted the main influence on this aspect of Robinson's thinking. Robinson was never significantly affected by leaders in the New History abroad, such as Karl

Lamprecht and his disciples in Germany, Henri Berr, Charles Seignobos, and Alfred Rambaud in France, or Guglielmo Ferrero and Corrado Barbagallo in Italy.

**Career and traits as a teacher.** Robinson's professional career as a teacher of history was spent at the University of Pennsylvania, Columbia University, and, for a brief terminal period, at the New School for Social Research in New York City. While in Germany Robinson had met Patten and evidently made a very favorable impression on him, for Patten induced his university to invite Robinson as a lecturer in history. He was made an associate professor in 1892 and held that rank until he was called to Columbia in 1895 as a professor of European history.

The work at Pennsylvania for which he was best known grew out of his conviction that a command of source material is mandatory for any historian, for the practitioner of the New History as much as for the most haughty traditionalist in the profession. From the beginning of his teaching career, therefore, he believed strongly that history students should read source material, and to this end he edited several volumes of "Translations and Reprints from the Original Sources of European History" (see works edited by Robinson in bibliography).

Robinson's call to Columbia was the result of the determination of Dean John W. Burgess of the faculty of political science to add a specialist in European history. Robinson was selected mainly because William A. Dunning had been attracted by Robinson's emphasis on source material and by his skill in editing the "Translations and Reprints." Dunning also believed that Robinson could help him in his work as editor of the *Political Science Quarterly*, which proved to be true.

Aside from the final period in Robinson's instruction, during which he roamed fruitfully over the whole historical record of mankind in his presentation of intellectual history, his courses dealt with the Middle Ages, the Renaissance, the Reformation, and the French Revolution. His original and very influential interpretations of each of these periods or movements rank next to his promotion of the New History in determining his role in American historiography; indeed, they were an early phase of his New History and were embodied in his later lectures on intellectual history.

Robinson vigorously criticized the traditional view of the Middle Ages as a unique millennium of uniform gloom and cultural collapse following a mythical fall of Rome in 476, and he maintained

that there was probably no sharper break in the whole history of western Europe than that which separated the earlier from the later Middle Ages. He viewed the Renaissance as a slow and gradual development from late medieval advances and held that the conventional conception of it as a sudden flowering of a new culture was a myth. He taught that it is equally false to believe that the Reformation grew out of the Renaissance; instead, he emphasized the sharply contrasting traits of the two events and maintained that the Reformation was more a national political movement than a sudden religious uprising. He contended that the most fruitful approach to the French Revolution lay in a study of its causes and the course of its development, with less attention given to its dramatic and sensational episodes, which were transient and of little institutional import.

Robinson's method of presenting historical material to his classes varied notably during the course of his teaching career. At the outset he was very energetic and systematic and presented his material in a carefully organized way. Cheyney said that it "was his habit [to write] an outline of his lecture on the blackboard before he began to talk to the students. I know it made a great impression on them to feel that he had in mind exactly the group of things he wanted to say, classified in the way he wanted to say them" (Letter to Barnes, March 3, 1926). At Columbia he appears to have become gradually more relaxed and informal. According to Carl Becker, the famed Cornell historian, who was a student of Robinson's in his first decade at Columbia, "The professor talked so informally and entertainingly that taking notes seemed out of place. He had wit, a dry, mordant humor, and a fund of striking, unacademic bits of information which I had not found in textbooks or formal histories; and there was a sadness in the countenance, a quality, half plaintiveness half resignation, in the voice that made even simple statements of fact amusing or illuminating, or both" (Becker 1937, p. 48). Toward the end of his second decade at Columbia, Robinson's classroom popularity was perhaps unsurpassed in the teaching of history in the United States, despite a lecture method that would have made any other teacher appear very dull. Arthur M. Schlesinger, a student of Robinson's around 1910, has given us one of the best characterizations of Robinson's classroom manner at this period: "His lectures . . . proved the most provocative of any I attended and triggered endless arguments among the students. . . . Peering quizzically above his spectacles and impishly salt-

ing his observations with wit, he spoke quietly, as though interviewing himself, with the class present merely as eavesdroppers" (Schlesinger 1963, pp. 34-35).

In retrospect it appears most unfortunate that Robinson resigned from Columbia in 1919 rather than remaining there until he reached formal retirement age in 1928. His brief experience at the New School for Social Research was unsatisfactory; it did not give him opportunities to lecture to large classes and was not the type of educational experiment he had anticipated.

**The New History.** Since Robinson stands out in the evolution of historiography and historical writing primarily as the most widely known and effective exponent of the New History, his role in this area requires a rather precise examination.

His most readily visible accomplishment was the volume entitled *The New History* (1912), a book that exerted a wide and enduring influence on American historical writing and thinking. This influence was due partly to the attention it attracted by its appropriate title, partly to its convenient presentation of most of Robinson's observations on what the New History should be. But the contents of the book were not "new" even to Robinson. The first chapter, on the contrasts between the new—or cultural—history and the old—or political, episodic, and biographical—history, had first appeared as an article in 1900, and the succeeding chapters were articles and addresses published in the first decade of the twentieth century.

More than that, as Robinson himself was sufficiently well read in the history of historical writing to know, the New History was not his exclusive progeny. Although he was little affected by his European predecessors and contemporaries who exemplified the New History, he was well aware of such books as Andrew D. White's *A History of the Warfare of Science With Theology in Christendom*, Moses Colt Tyler's *Literary History of the American Revolution: 1763-1783*, H. C. Lea's work on the medieval church, Henry Adams' *Mont-Saint-Michel and Chartres*, and the work done by Frederick Jackson Turner and his students on the effect of the western frontier upon American culture and thought, to mention only a few of the authors who had already abandoned the older political and episodic history. What Robinson did was to christen the new departure in historical thought and writing, to found a movement around it, and actually to write exemplary history in terms of his conception of the subject.

Robinson's own development as the leading pro-

tagonist of the New History was a gradual one. As early as 1892, when he served on the Committee on Secondary School Studies of the National Education Association, he had enunciated what was to be a main tenet of his conception of the New History: that history should be written and taught in such a manner as to enable students to understand the conditions of their own time. He amplified this while serving on the 1904 Committee of the Association of History Teachers of the Middle States and Maryland, and he also advocated giving greater attention to modern history and world history. His collaboration with Beard on *The Development of Modern Europe* (Robinson & Beard 1907-1908) gave him a better comprehension of the importance of economic factors, especially of the industrial revolution, in the historical experience of mankind (see chapter 5 of *The New History* [1912] 1958, pp. 132-153).

Robinson's conception of the New History inevitably inclined him to regard history as a social science rather than as a branch of literature or an exercise in "collective biography." He was one of the first historians to call attention to the indispensable services of the social sciences to history, notably in his address before the American Historical Association in December 1910, entitled "The Relation of History to the Newer Sciences of Man," which constitutes the third chapter of *The New History* (*ibid.*, pp. 70-100). The fourth and the final chapters of *The New History* indicated Robinson's shift of interest to intellectual history, where he believed particularly strategic material could be found for the use of history in the service of social improvement. This was a theme he developed further about a decade later in two brief books, *The Mind in the Making* (1921), and *The Humanizing of Knowledge* (1923).

In his program of interpreting history and applying its lessons for the improvement of society, present and future, Robinson wrote many articles for historical periodicals in the 1920s and 1930s. These were brought together by Harry Elmer Barnes in a symposium entitled *The Human Comedy* (1937). The book is far and away the most comprehensive and revealing of all of the publications which present Robinson's contributions, containing as it does many of the important ideas that may be found in his other works and specific coverage of most of the leading topics and problems of modern history and contemporary life.

Textbooks. While it is rather commonly believed that Robinson's main contributions to the concepts and development of the New History are to be found in his writings about history, it seems

highly probable that he did far more to communicate his ideas about the nature and purpose of history by making them the core of his popular and widely used textbooks. The first and most revolutionary of these was *An Introduction to the History of Western Europe* (1902-1903), which was immediately followed by two volumes of *Readings in European History* (Robinson & Beard 1908-1909). Into the 1903 volume Robinson put his best thought and put it very well, this being the time of his maximum intellectual vigor and enthusiasm. This work set an entirely new standard for textbook writing in the historical field.

The outstanding aspect of the *Introduction to the History of Western Europe* lay in the author's successful discerning of the leading threads of medieval and modern European history and his tracing them with clarity and consistency. While he included all the political history that was necessary to understand the changing structures of European institutional life, he abandoned the traditional view that "history is past politics" and introduced ample material on social, cultural, and intellectual life. All this material was presented with Robinson's human touch and sprightly style, which gave vividness to the narrative and made it enjoyable to read. His readers were left unaware that Robinson's fluid prose was based on a rigorous study of the original sources which "controlled with relentless precision his reconstruction of the past," as his famed student, James Thomson Shotwell, insisted (Letter to Barnes, April 15, 1926).

Although the work ran counter to all precedent in the textbook field, it produced such a striking and favorable reaction on the part of history teachers that for more than a generation it dominated the college market. Over a quarter of a million copies of the first edition were sold. Admittedly, it was weak in treating the economic factors in history, especially in the modern period, and English constitutional history was given scanty attention. These defects were remedied in later editions after Robinson came into greater contact with Beard and collaborated with him in producing *The Development of Modern Europe*.

Robinson's influence in making the New History the basis of history teaching was extended to the secondary schools for many years through the two volumes of *Outlines of European History*, published in 1912-1914 (Robinson et al. 1912-1914). Robinson's collaborators in this instance were James H. Breasted of the University of Chicago and again Beard, with Breasted covering the ancient period and Beard giving primary attention to the treatment of economic factors in modern times. Revised

and adapted with the assistance of Emma Peters Smith and others, the work sold well until after Robinson's death. But there was little vital material in it that had not appeared in his college books, and by the 1920s, writers like Hutton Webster were producing texts that surpassed Robinson's in presenting the New History in fresh and original ways for the secondary schools.

**From teacher to preacher of history.** Between 1900 and 1912 Robinson was active and energetic in writing substantial, pioneer textbooks and in producing the articles and addresses that came to make up *The New History*. In the quarter of a century that followed 1912, an evident change took place, affecting both his professional life and his zest for writing. Robinson became wealthy and independent through his textbook royalties, but also increasingly relaxed in most matters, except for his ideas about history. Moreover, he loved to talk, was a witty and intriguing conversationalist, and spent more and more time talking to his favorite colleagues like Dewey, Thorndike, and Wilson. Beard was inclined to think that this did more than anything else to distract Robinson from further substantial historical publications, and may have accounted for his failure to produce his expected magnum opus on the history of the intellectual class in western Europe. Although Robinson was still a relatively young man in 1907 when *The Development of Modern Europe* (Robinson & Beard 1907-1908) was published, he never produced another historical volume of the scale and quality of this book and of his original *Introduction to the History of Western Europe*.

As Robinson devoted himself more and more to thinking and talking about history rather than writing it, he gave increased attention to interpreting history and to considering what service it might render to the understanding and betterment of mankind. As Lynn Thorndike put it,

The chief change that came over Professor Robinson in the course of his life . . . was that from being a teacher of history he became a preacher of history. The small seminars and informal classes gave way to crowded lectures and these to a host of readers. . . . He would humanize knowledge. While some of us are content with the hope that our ideas and findings may gradually filter down through our students and learned publications to have their ultimate effect on human thought and society, Robinson was impelled to make more direct contacts. Despite his critical attitude toward past and existing religion, he had the faith not merely that would move mountains but would move muttonheads. (Thorndike 1937, p. 369)

**The Columbia school of New Historians.** Robinson's associates were tied together not so much by

their common interest in a particular subject of investigation but by a common attitude toward the nature and purpose of history in general and by a sort of filial devotion to Robinson. The nature of the so-called "Robinson school" has been well stated by Crane Brinton: ". . . around Mr. Robinson and other leaders a definite, self-conscious school of historians has formed, and . . . this school has cohesion, common purposes, common watchwords, common loves and hatreds . . . in short, it is a school in the good, loose sense in which the Stoa, the Pleiad, the Lake poets, or the Utilitarians were schools" (Brinton 1936, p. 134).

Writers from this school produced creditable, and in some cases impressive, works in many fields. In the area of intellectual history probably the most important were the able editorial work and translations of church and medieval historical works and documents by Louise R. Loomis, Ernest Brehaut, and Irving W. Raymond; the massively erudite volumes of Lynn Thorndike on the history of European magic and science; Alexander C. Flick's substantial treatment of the medieval church; the definitive writings of Preserved Smith on the Renaissance and Reformation and the intellectual life of the seventeenth and eighteenth centuries; Dorothy Stimson's account of the impact of the Copernican system; Martha Ornstein's brilliant work on the rise of the scientific societies; Becker's influential interpretations of the intellectual backgrounds of the English, American, and French revolutions; the work of Howard Robinson on French rationalism; Anne E. Burlingame's study of Condorcet; J. Salwyn Schapiro's treatment of modern French liberal and revolutionary thought; Carlton Hayes's writings on the nature, ramifications, and influence of nationalism; and J. H. Randall, Jr.'s monumental history of European philosophy and thought. The Robinsonian emphasis on social history was applied in American as well as in European history, by Beard, Schlesinger, Harold U. Faulkner, Dixon Ryan Fox, and Harry J. Carman. Robinson's interests in historiography were carried on mainly by Shotwell and Barnes, with some incidental but valuable contributions by Schlesinger and Henry Johnson. The only one of Robinson's disciples who gave special attention to social reform and amelioration was Barnes, who did this as much in his role as sociologist and criminologist as in that of historian.

It was Barnes also who produced the only comprehensive synthetic works in the Robinsonian tradition, of which the first was *A History of Western Civilization* (Barnes & David 1935). Robinson himself lived to read, review, and approve of this

work. Crane Brinton, although somewhat critical of the Robinsonians, characterized the book as "this advertised inheritance, this harvest of a long tradition, this long-awaited fruition" of the Columbia school (Brinton 1936, p. 135); and Preserved Smith described it as "incontestably the masterpiece of the New History" (Letter to Barnes, Sept. 6, 1935). Barnes next endeavored to fill the gap created by Robinson's failure to produce his intellectual history. Aided by experts in the history of art, literature, and music—subjects with which Robinson did not deal extensively in his writings—Barnes produced the *Intellectual and Cultural History of the Western World* (1937), a more comprehensive work than Robinson had ever planned.

In 1929 a symposium entitled *Essays in Intellectual History*, containing contributions by some of Robinson's leading students in this field, was presented to him at the time of his election to the presidency of the American Historical Association. This testimonial volume attested to the distinction of his students and to the diversity of interests that he stimulated.

As an appraisal of the significance of the Robinsonian epoch in historical writing one may conclude with the critical and restrained summation by Brinton:

Now the battle to free history from the limitation of the doctrine that history is "past politics" . . . has been won, and won largely through the efforts of the Columbians. With all their faults, the history text-books of today afford a far more nourishing fare than did the text-books which Mr. Robinson ridiculed so effectively in *The New History*. . . . The battle against purely political history was worth fighting, and the victory worth winning. (Brinton 1936, p. 135)

#### RODBERTUS, JOHANN KARL

Johann Karl Rodbertus (1805-1875), also known as Rodbertus-Jagetzow, was born in Greifswald, Pomerania, then under Swedish jurisdiction, where his father was a professor of Roman law and a member of the Swedish judiciary. His

mother was the daughter of Johann August Schlettwein, a physiocrat and professor of statistics and political economy. After Napoleon's troops occupied Greifswald, the elder Rodbertus resigned his post, in 1808, and withdrew with his family to one of the Schlettwein estates. Rodbertus then attended the Gymnasium in Friedland, Mecklenburg, an institution permeated with the liberalism of that period. His subsequent study of law in Göttingen and Berlin, from 1823 to 1826, led to his service as a barrister to the Prussian state. In 1832 he left government service and turned to the study of political economy, first in Dresden and then in Heidelberg, supplementing his academic studies with travel in Switzerland, France, and Holland. There he became aware of the grave social tensions related to industrialization, and these remained his concern to the end of his life.

Rodbertus was a German state socialist, as were Ferdinand Lassalle and Adolf Wagner. He was in constant correspondence with these two men, and their mutual influence is unmistakable, particularly that between Rodbertus and Lassalle. These two agreed that given the existing political and legal order and the institution of private property in capital and land that was based on it, there was no hope of solving the "social problem" (i.e., the social disorganization attendant on the industrial revolution). Yet Rodbertus and Lassalle differed in their approaches to the modification of the existing order: Lassalle sought to achieve his aims by forming a political party—a social democratic party—while Rodbertus insisted that the socialist movement concern itself only with economic matters and abstain from all political aims.

Rodbertus' diagnosis of the ills of society begins with an analysis of the economic and social effects of private property. In an economic system based on private property, labor becomes a commodity and land becomes capital. If the private ownership of land and the means of production were eliminated, all goods might, from the economic point of view, be considered products of labor. Their value, then, would depend exclusively on the amount of labor required for their production. The existence in the economic system of capital rent (interest) and land rent was attributed by Rodbertus to two causes, one economic and one legal. The economic cause is the fact that the division of labor and advancing production technology enable the worker to produce more than he requires for his own support. The legal cause lies in the protection by law of private ownership of land and of the means of production. Both the peasants and the workers may therefore be

charged by the owners for the use of their property, and the charge that is exacted takes the form of part of the product of labor. Rodbertus called this "rental profit," which in turn can be divided into land rent and capital rent.

According to Rodbertus' theory of labor value, capital rent is independent of the total capital, deriving only from that part of capital which is expended on labor. Since rent represents the ratio of the surplus value levied to the capital invested by the entrepreneur, it is lower in industry than in agricultural production, where the soil, as a gratuitous means of production, contributes its own fertility to output. Hence, what Rodbertus called an "absolute land rent" is derived from the soil, and the soil should be considered as a rent fund rather than as capital. The implication of this theory of rent for agrarian policy is, according to Rodbertus, that land should not be encumbered with capital debt but only with the obligation of paying rent. He believed that mortgage indebtedness should be replaced by payment of permanently fixed rent. This proposal was effected in part, and only temporarily, by the establishment of so-called rent estates.

As Rodbertus saw it, the moral development of man is impeded by a social system that, by virtue of private ownership of land and of the means of production, turns labor into a commodity and land into capital. For the sake of the community as a whole, over and above that of the individual, it was necessary to change the system. Unlike Marx, Rodbertus did not believe that change had to be revolutionary; his conception of change was influenced by Fichte and Schelling and was evolutionary in nature. To be sure, Rodbertus did not believe that mankind would simply evolve toward an ideal type; rather, he thought that ever-increasing economic entanglements would impel men to effect remedial political action. Only in the remote future would the process of historical evolution result in a society organized on a moral basis, with the total elimination of private ownership of the means of production and of land. Such a social-historical conception—it has also been termed metaphysical collectivism—was hardly practical, and it is not surprising that Rodbertus' doctrines had little or no influence on the German labor movement.

The basic principles of Rodbertus' social philosophy (later supplemented by his political economy) were first presented in an article entitled "Die Forderungen der arbeitenden Klassen" (submitted to the *Augsburger Allgemeine Zeitung* in 1837 or 1839, but not accepted by that news-

paper). Rodbertus believed that a social order must be based on one of two systems: either that of discipline and subordination, or that of education (which in turn is based on upbringing and instruction). In antiquity, the social order was of necessity based on discipline and subordination; Rodbertus believed slavery and exploitation to be justified as long as the productivity of the economy was so low as to support adequately only the cultured stratum of society. But with the growth of productivity, the poorer strata should be granted a share in the social product over and above the subsistence level. If this does not occur and only the few continue to benefit from the increased flow of goods, it is because obsolete juridical and economic institutions are vitiating proper distribution, and it means that the social order requires modification.

What makes for this "wrong" distribution is the iron law of wages, by virtue of which the social product is so distributed among landowners, capitalists, and workers that the last receive a constant amount, and hence a constantly diminishing share, despite rising productivity. In an age when discipline and slavery no longer serve as the underlying principles of social organization but have been replaced by education, nothing can save society from collapse so long as the workers' misery and poverty "destroy what the school is trying to accomplish" (1839, p. 16). There is then a fundamental defect in those legal and economic institutions that permit the iron law of wages to drive the classes of society increasingly apart and thus to imperil the progress of civilization and the very existence of culture.

Only government intervention, Rodbertus believed, can counteract what he called the law of the decreasing wage share. The rent received by capitalists and landowners should be abolished, thus eliminating "rent-receiving private property," at the same time that the workers' ownership of the product of labor is guaranteed. Rodbertus proposed that the average labor time spent on production determine the distribution of the social product. (For Rodbertus' related concept of the "normal working day," see his 1871 article.) Each worker should receive a confirmed claim to products collected in a storehouse, corresponding to his contribution in terms of labor time. A new currency of constant value can be introduced in this manner. (It is worth noting the failure of Robert Owen's attempt, in 1833, to establish a labor exchange.)

Rodbertus' researches in economic history served to support various aspects of his theoretical system—for example, his assertion that originally

there was only a single rent, which became differentiated into land rent and interest on capital with the introduction of the division of labor. His conception of the historical relativity of economic conditions led him to reject revolutionary demands, on theoretical as well as political grounds. Politically, he considered every revolution a detour, since it involved the destruction of law and order; as a theorist, he advocated a guided "system of social foresight" in lieu of *laissez-faire*. He was not in favor of tampering with the current distribution of property; only its "fruits" (interest on capital and land) should be redistributed by governmental measures.

## ROGERS, JAMES E. THOROLD

James Edwin Thorold Rogers (1823-1890), one of the founders of modern British economic history, was a vigorous and versatile scholar whose forceful personality and uninhibited political partisanship directly affected his academic career. As an interpretative historian, he consistently stressed the economic basis of political issues. His personality is evident throughout his historical writings, especially in his prefaces; he repeatedly denounced the follies and injustices of his own and previous generations and boldly asserted his claims to originality and pre-eminence in his chosen field of research.

Rogers' life began conventionally enough. He was born at West Meon, Hampshire, and after studying at Southampton School and King's College, London, he graduated from Magdalen College, Oxford in 1846, the year of Richard Cobden's free-trade triumph. An ardent High-churchman, he was ordained at Oxford, where he combined his clerical duties with a successful career as private tutor in classics and philosophy, examiner, and holder of various unpaid university administrative posts. About 1860, however, the whole pattern of his life changed. He abandoned the church because of his increasing dissatisfaction with the Tractarian movement and became a leading supporter of the Clerical Disabilities Relief Act of 1870—which he was the first to avail himself of. He turned from the classics to economic subjects, partly in response to suggestions made at the International Statistical Congress and partly because the Clarendon Press had refused to publish his Aristotelian dictionary. In 1861 he published *Education in Oxford: Its Methods, Its Aids, and Its Rewards*, which contained many severe criticisms of the university. He had already, in 1859, been appointed Tooke professor of statistics and economic science at King's College, London, a post he retained until his death, and in 1862 he also became Drummond professor

of political economy at Oxford, nominally a five-year appointment. Rogers' tenure was characteristically energetic. He delivered frequent lectures enlivened by racy anecdotes and incisive comments on contemporary personalities and issues, and he published the first two volumes of his monumental *History of Agriculture and Prices in England* in 1866, as well as other works on political economy, ethics, law, and politics. Nevertheless, he failed to secure re-election in 1868, owing to a vigorous campaign by members of convocation who objected to his strictures on Oxford and his outspoken radical opinions.

This defeat reinforced Rogers' iconoclasm and drew him inexorably toward politics, a field which brought out the boisterous and intemperate side of his nature. His political ideas were deeply influenced by his intimacy with Richard Cobden, whose sister had married Rogers' elder brother. Rogers edited Cobden's and Bright's speeches (see Cobden 1870; Bright 1879), and the essays in his *Cobden and Modern Political Opinion* (1873) reveal his staunch adherence to free trade. In 1880, after an earlier unsuccessful candidacy, he entered the House of Commons and remained a member for six years. But he was neither a conspicuously successful nor active parliamentarian, for he continued to live at Oxford and pursue his scholarly activities. His most important writings include *Six Centuries of Work and Wages* (1884), which contains the preliminary results of his indefatigable researches, and four additional volumes of his *History of Agriculture and Prices*, which appeared in 1887. Volume 7, in two parts, was published posthumously, as was a volume of lectures, *The Industrial and Commercial History of England* (1892). These, like his earlier lectures entitled *The Economic Interpretation of History* (1888a), were delivered at Oxford, where Rogers was re-elected to the Drummond chair in 1888, following the death of Bonamy Price, his rival of the 1860s. This reinstatement was widely interpreted as an effort to make restitution for the earlier injustice, a verdict which Rogers himself did nothing to discourage.

As a scholar Rogers was too wayward, too much influenced by personal likes and dislikes. His scathing comments on Ricardo's and Malthus' "metaphysical" school of English political economy and his insistence on the need to base economic principles on an exhaustive examination of the facts made him a natural ally of the historical economists, who were attacking the doctrines and methods of classical economics during the 1870s and 1880s. Yet he was far too idiosyncratic to be a

faithful member of any doctrinal school. Indeed, he greatly exaggerated his disagreements with Ricardo and Malthus, and in contrast to the historicists, he was profoundly influenced by Frédéric Bastiat's laissez-faire ideas. Admittedly, he qualified his earlier uncritical adherence to the wages-fund doctrine and became a warm advocate of trade unions; but he made only minor concessions to those who desired an increase in government intervention in economic and social life.

As a historian Rogers was a great pioneer, but he lacked the indispensable qualities of modesty and caution. In contrast to his painstaking accumulations of price data, which he published with indiscriminating zeal, he made many sweeping and uncritical judgments about the past. His conviction that "all genuine facts are far more valuable than the inferences of any individual who uses them" (1866–1902, vol. 4, p. vi) was, therefore, borne out in his own case. At a time when historians were being increasingly influenced by evolutionary ideas, Rogers' approach to the past was, as one contemporary critic observed, "cataclysmic" (Ashley 1889, p. 400; see also Gibbins 1891). He seriously overrated the pernicious influence of governmental policies, past and present, but his hostility toward all forms of privilege, his distaste for the governing classes, and his sympathy toward the workers made his books acceptable to several generations of students, especially in the world of adult education. Through this medium, in conjunction with Arnold Toynbee, Rogers helped to popularize the pessimistic view of the consequences of the industrial revolution that dominated English economic history almost until the 1940s.

## RÓHEIM, GÉZA

Géza Róheim, anthropologist and psychoanalyst, was born in Budapest in 1891 and died in New York in 1953. Róheim came from a family of wealthy merchants. Even in his preschool years he showed a more than ordinary interest in myths and fairy tales, and while still a high school student he became an expert in Hungarian folklore. At the age of 18 he wrote an essay, "Dragons and Dragon Killers" (1911), that presaged some of his later psychological and cultural theories. Róheim's interest in mythology and folklore continued throughout his life: when he was only five he read *Alice*

in *Wonderland* and the *Arabian Nights*, and in his last major work, *The Gates of the Dream* (1952), he discussed what he considered to be one of the basic themes of *Alice*, her fall into the rabbit hole.

Róheim attended the University of Budapest, until his interest in ethnographic research led him to the University of Leipzig to study under Karl Weule and to the University of Berlin to study under Felix von Luschan. While in Germany, he became acquainted with Freud's writings, including the psychoanalytic interpretation of culture first proposed in *Totem and Taboo*.

After having received his PH.D., Róheim returned to Budapest, where he became a staff member of the Hungarian National Museum. It was at this time that he underwent his first psychoanalysis, with Sándor Ferenczi. The dual nature of Róheim's training made it possible for him to do pioneering work as the first psychoanalytic anthropologist. His work in the early 1920s clearly reveals his unusual conceptual equipment. In 1921 he delivered a paper on Australian totemism (published in an extended version in 1925), for which he received the Freud prize in applied psychoanalysis. In the same year, he published a paper on "Das Selbst" ("The Self") that anticipated psychoanalytic ego psychology by almost two decades. Again, Róheim's treatise "Nach dem Tode des Urvaters" (1923) reveals his application of anthropological research to Freudian concepts. Although he accepted Freud's postulation of the primal horde and the Cyclopean family, Róheim insisted that the "eating of the overlord" represented nothing more than the reversion to a fantasy pertaining to the oral stage of human development. This theory foreshadowed his shift from Freud's phylogenetic explanation of culture (in terms of the sense of guilt and the experience of sin and atonement, arising from Oedipal conflicts during the phallic stage) to an ontogenetic one.

With the encouragement of Freud himself, and assisted by Princess Marie Bonaparte, another of Freud's disciples, Róheim sought to find anthropological evidence to validate Freud's theories and set out in 1928 on the first field expedition undertaken by a psychoanalytically trained anthropologist. His research was particularly focused on the western tribes of central Australia (Aranda, Pitche-tara, Pindupi, Yumu, Nambutji). His stay in central Australia was followed by a nine-month visit to Sipupu, Normanby Island, in the D'Entrecasteaux group. His aim was to study a matrilineal society closely resembling that of the Trobrianders, whom Malinowski had made the focus of his field

observations. Róheim also visited briefly among the Yuma Indians on the borders of California, Arizona, and New Mexico. It was his research among the Australian aborigines, however, that provided the basis for his revised psychoanalytic theories.

Freud's conception of the relationship between human culture (particularly totemism, religion, and social structure) and the vicissitudes of the primal family has found little confirmation in biological or anthropological evidence. Some evidence for the Cyclopean family, as conceived by Freud, may be adduced from the life of anthropoids, especially that of the baboon horde (Zuckerman 1932), but it must be remembered that this study was made of apes in captivity. Although the primal horde theory does seem to be useful in the interpretation of numerous myths and religious practices, serious doubt as to the validity of the hypothesis that memories may be inherited led Róheim to base his field work and his clinical observations on the theory that cultural patterns and institutions can be explained in large measure by the biologically conditioned crucial role of the specific infantile situation, such as separation anxiety, together with the largely environmentally conditioned prevailing libidinal trend.

Róheim thus proposed an ontogenetic theory of culture, with special emphasis on the role of biology and anatomy, that depended heavily on the findings of the Dutch anatomist Louis Bolk (1926). According to Bolk, comparative morphology reveals that the human individual shows many traits of neoteny, such as hairlessness, the form of the ear muscles, Mongoloid development, orthognathia, the central position of the *foramen magnum*, relative brain weight, certain variations of the jaw, persistent cranial sutures, and the tendency toward brachycephalization. However, among the higher anthropoids, the eruption of the milk teeth starts almost immediately after birth, and shortly after the growth of the second milk molar the first permanent one appears. This rather rapid change demands an equally rapid development of the jaw as well as of the entire skull. In man, on the other hand, there are two intervals that impose retardation. The milk teeth are fully grown only toward the end of the second year, so that the human child depends on sucking rather than on biting for a much longer period. After the second year there is an interval of about four years before the first permanent molars come through.

The psychological consequences of neoteny, according to Róheim and additional explorations by Muensterberger, stem chiefly from man's prolonged

dependence on maternal care. The so-called ego functions reflect the long period of human infancy; indeed, the various psychological processes do not reach maturity until the second decade of life. The human child, more than any other mammal, is in constant need of protection and nourishment provided by an external agency. The bond created by physiological necessity develops into a necessary emotional and social tie, forcing the human being to attain and maintain continuous relationships with other people. Like several other psychoanalysts, Róheim considered this dual bond to be a peculiarly human predicament. Moreover, this protracted symbiotic relationship forms the nucleus of wider social cohesion and organization. In its negative aspect of dependence and jealousy, it is the source of feelings of anxiety and helplessness and of fears of castration and separation.

This uniquely human dual bond leads to the differentiation of ego and nonego, of a self and an external world. It produces man's predominant aim, which is to gain contentment and happiness and to avoid discontent and disillusionment. Attachment to the mother is the first source of pleasure, and disillusionment and anxiety are created by her absence. Thus, from a psychobiological point of view, the human organism can discharge tension only through another organism; the infant is anaclitic. The dual bond also leads to the differentiation of ego and id, which are essentially one in lower animals. "Instincts" (built-in behavior patterns) are replaced by learned behavior patterns.

Róheim's dream theory is constructed on the analogy of the infantile experience of initial acceptance of the outside world as only an intermediary aim on the path of withdrawal from that world. His emphasis on the significance of particular fantasies experienced during the process of falling asleep is related to his ontogenetic approach. He related the sense of *falling* that is characteristic of the hypnagogic state to the inherent desire to return to the dual-unity situation that denies the separation of the child from the mother. He suggested that in sleep we return to the intrauterine situation and that dreams are attempts to re-establish contact with reality. In other words, dreams are efforts to reverse the regressive condition caused by sleep and therefore constitute a defense against the reinfantilization represented by sleep.

The ontogenetic theory of culture explains man's pattern of separation (anxiety, ambivalence, aggression) and subsequent reunion as a repetition of the fundamental duality of the mother-child relationship. The reaction to absence or frustra-

tion is aggression and/or anxiety. The pattern also appears in numerous primitive ceremonies and religious rituals, including the killing and oral introjection of the totem animal, behavior which, according to Róheim, represents aggression as a reaction to separation anxiety, followed by reunion or the covenant (1945). Similarly, the Oedipus complex is not the result of inherited memory images; it is the inevitable outcome of the human family and its extended period of infancy. Totemism, in this view, is merely one of the most frequently used of the several available solutions to the Oedipal nature of man.

Using his own field observations as examples, Róheim was able to show the development of specific cultural patterns or group ideals. Among the aborigines of central Australia, the typical infantile trauma is the *alknarintja* situation: the mother lies on top of the boy infant, ostensibly to protect the child. Evidence from myths, dreams, and rituals suggests that the child experiences this "protection" as a threat to himself when he is in a helpless, passive, inverted position. The institution of phallic ceremonialism, based on the exclusion of women and the projection of the threatening mother image onto the dangerous phallic female demons, is an attempt to ward off the early traumatization of the boy infant. Thus, this simple example from Pitche-tara society shows how the crucial elements in the infantile situation lead to reaction formations, which then become institutionalized. The smaller and more self-sufficient a society, the greater the likelihood that specific cultural patterns in the relationship between mother and child will produce a prevalent personality type in the society, that is, a greater psychological similarity among the members of that society.

As Róheim put it: "Man has invented culture because of his delayed infancy or intolerance of tension. In our own attempt to master reality we create a society, i.e., a well-functioning symbiotic mode of existence. Instead of parricide and incest, we have the super-ego and group formation, instead of 'clutchings' to archaic objects we have 'seekings' of new substitute objects. Adaptation then becomes a favorable solution between narcissism and object-cathexis" (1943, pp. 77-80). Hence, in Róheim's view, culture is a defense system against the fear of object loss and the separation anxiety that sacrifices immediate gratification and the monopolization of maternal love for a modicum of security and partial gratification.

## ROLE

## I. PSYCHOLOGICAL ASPECTS

Theodore R. Sarbin

## II. SOCIOLOGICAL ASPECTS

Ralph H. Turner

## I

## PSYCHOLOGICAL ASPECTS

The concept of role came into psychology through the cross-disciplinary efforts of a number of social and clinical psychologists. The dramatic metaphor was first systematically exploited by George H. Mead and the University of Chicago sociologists in the 1920s. Its utility was demonstrated particularly in connection with the analysis of occupational and quasi-occupational categories. In the 1930s and 1940s several writers opened the way for social scientists to employ the concept in the analysis of interpersonal behavior. Among them were Moreno (1934), who pioneered the use of role playing as a tool of psychotherapy and role training; Sarbin (1943), who analyzed hypnotic behavior as role enactment; Cameron (1947), who demonstrated how the behavior of disordered persons could be understood as faulty role enactment, as failure in taking the role-of-the-other, and as ineptness in playing out one's socially assigned roles; and Newcomb (1950),

who used role as a central concept in his social psychology. Several writers have characterized role as the construct that bridges psychology and the other social sciences. It connotes not only overt actions and performances but also covert expectations held by an observer, or by a group of observers, such expectations serving as the basis for judging the propriety of the enactment. The concept of role is now widely used in the study of industrial and bureaucratic organizations, the family, small-group interaction, behavior modification, attitude change, behavior pathology, and recently, the analysis of psychological experiments where persons are assigned the role of experimental subject.

**Definition of role.** In general, the term "role" continues to be used to represent the behavior expected of the occupant of a given position or status. Thus, following the implication of the dramaturgical metaphor, an actor assigned to the position (or part) of Hamlet is expected to enact the role of Hamlet, the role being characterized by certain actions and qualities. A person who is assigned to the position of clergyman (or who elects to be placed in such a position in the social structure) is similarly expected to enact the role of clergyman characterized by certain typical actions and qualities. In this definition two features are emphasized: (1) *expectations* (i.e., beliefs, cognitions) held by certain persons in regard to what behaviors are appropriate for the occupant of a given position, and (2) *enactments* (i.e., conduct) of a person who is assigned to, or elects to enter, a given position.

## Role enactment

Although the definition given above is satisfactory as a first approximation to the analysis of ongoing social behavior, more refined analysis has demanded the introduction of concepts that are more differentiated. In the first place, the behavior that serves as the dependent, or outcome, variable is seen as *role enactment*. That is, interest is focused on what the occupant of a given position *does and says*, such behaviors being noted by observers who may use behavior rating scales or free response verbalizations to make known their observations. Needless to say, the effectiveness, convincingness, validity, or propriety of such role enactments varies between persons and situations. To uncover the antecedents of this variation, social scientists have introduced additional theoretical conceptions and observational procedures. Among the variables that have been demonstrated to be antecedent to variation in effectiveness or

propriety of role enactment are (1) validity of role expectations held by the actor, (2) accuracy of the actor in locating the other(s) (and reciprocally the self) in the proper role system, (3) sensitivity to situationally generated role demands, (4) available general and specific skills, (5) congruence of self and role, and (6) reinforcement properties of the audience. Each of the variables will be discussed below.

**Role expectations.** In order effectively to perform, i.e., to validate his occupancy of a social position, the actor must learn—either at first hand or vicariously—what performances are associated with what positions. In short, he must be acquainted with at least certain sectors of the social system: he must know what obligations, privileges, rights, and duties are the defining characteristics of each position he may be called on to occupy. Given such knowledge, he is in a better position to enact an assigned or ascribed role. The concept of role expectation is implicit in many practices in contemporary society. College students, for example, are frequently participants in orientation programs designed to provide them with the proper role expectations. Induction into the military or into bureaucratic organizations is similarly designed to acquaint inductees with their rights and privileges and with their duties and obligations. Failure to acquire expectations for recurring roles leads to enactments that are judged as inept, invalid, improper, antisocial, or illegal.

Role expectations may be viewed as *actions* or *qualities* expected of the occupant of a position. If viewed as actions, role expectations are codified as in a job description: the occupant is expected, for instance, to call the roll, open the windows, secure the doors. If viewed as qualities, role expectations are codified in adjectival terms; for example, the occupant is expected to be warm, friendly, outgoing, sincere, and cautious. This account of role expectations is necessarily oversimplified. Persons usually occupy multiple positions, some of which may be considered compatible, such as professor, father, and scientist, and some considered incompatible, such as high school teacher and bartender. The resolution of such incompatibilities has been studied in a number of contexts. These studies have provided us with a recognition of institutionalized rituals and personal adaptive techniques that serve to reduce the strain attendant upon occupying incompatible roles. In addition, the occupant of a position not only enacts role behavior that is congruent with the expectations held by others in the macrocosmic social system but also performs acts that make good his occu-

pancy of concurrent positions in microcosmic personal role systems. Whereas the macrosystem points to the kinds of role behaviors appropriate to regularly occurring situations, miniature systems develop where the role expectations must be expressed in terms separate from the more obvious task expectations of the macrosystem. These may be denoted as idiosyncratic preferences, nonconsensual expectations, and subtle or disguised expectations. Goffman (1961) has provided some enlightening illustrations of this notion under the rubric "encounters." In a surgical team, for example, the chief surgeon may not only direct the flow of activities that are task oriented, thus meeting the expectations for surgeon, but also engage in behavior unrelated to the surgical task—such as making jokes—designed to maintain an optimal degree of tension in the performers.

The problems of assessing role expectations are no different from the problems of assessing any inferred variable. Expectations must be inferred from overt conduct, including self-reports, and from samples of behavior in unstructured test situations. An investigator may assess the role expectations held by a group of persons by observing their conduct in situations where an actor emits behavior in response to standard problems. Or he may make his inferences from replies to more direct questions, such as "What behavior should one typically expect from a person who is in the position of school superintendent?" Various devices have been created for more systematic investigation of role expectations, such as role inventories, designed to get at the *actions* expected of the occupant of a position, and adjective check lists and rating scales, designed to get at the *qualities* or personal dispositions expected of the occupant (Sarbin & Jones 1955).

**Role perception.** It is axiomatic that in order to survive as a member of a society, a person must be able to locate himself accurately in the role structure. The simplest way to accomplish this is by seeking and finding answers to the question "Who am I?" Since roles are structured in reciprocal fashion, the answers can also be achieved through locating the position of the other by implicitly asking the question "Who are you?" The answers to the latter question are usually phrased in terms of role categories, such as man, teacher, friend, officer, secretary, and clown. In order to establish the position of the other, the actor must pay attention to the behaviors emitted by that other, scanning for cues that have reliability and validity. Physique and figure, hairstyle, facial adornment, and dress, among other things, are

cues to which the actor may attend in order to locate the other, and reciprocally the self, in social space. The process of enculturation is heavily weighted with the learning of which emitted behaviors are signs or cues for which positions in the social structure. In ambiguous or partially structured situations, the actor may influence the role of the other by casting himself in one rather than another permitted role. His behavior, in short, serves as a potential constraint on the role enactment of the other, who must also locate himself in the social structure.

Under ordinary conditions the location of the other in social space occurs without much reflection, partly because much social behavior is ritualized, partly because the "badges of office" are more or less obvious. To locate the position of the other it is sometimes necessary to infer covert behavior on the part of the other, such as "feelings," expectations, and attitudes. The more obvious cues and badges of office may not provide necessary information for correctly classifying the other. In this case the actor may search the ecology for additional cues, such as might be emitted in the form of posture, linguistic forms, facial expression, and gesture. Illustrative empirical research arising from this conception are two studies carried out in an effort to establish the relationship between accuracy of role perception on the basis of postural cues and indices of deviant or maladjusted role enactment. Sarbin and Hardyck (1955) constructed 43 stick figures in which all cues except postural ones were eliminated. These stick figures, black-and-white line drawings schematically depicting human postures, are presented one at a time to the subject, who selects, from among 5 choices, a word or phrase descriptive of the stimulus object. On standardizing groups, the frequencies of response to the 5 choices follow a J curve, the modal response containing at least 70 per cent of the distribution. When a subject's protocol for the 43 stick figures shows a high proportion of modal responses, his performance is designated as *conformant*. Inmates of a state mental hospital who were classified as schizophrenic (whose deviant role enactments presumably were instrumental in establishing residence in the hospital) selected the modal response choice no more often than the low response choices.

A further study (Krasner et al. 1964) made use of a more refined scoring system. Those stick figures whose modal responses were terms indicating *covert* states, such as thinking, sadness, and anger, were scored apart from those stimuli whose modal responses were terms representing

more overt conduct, such as running, sleeping, and standing at attention. Comparison of the performances of nonhospitalized control groups with hospital patients classified as schizophrenic showed significant differences in scores for the inference items but no significant differences for the non-inference items. This finding lends support to the proposition that the conduct of persons classified as exhibiting deviant role enactment (i.e., mental patients) is characterized by errors in locating others in the role system when they must depend on interpreting cues that represent covert states or dispositions.

Stated in an alternate form, the role perception variable considers the cue properties of the ecology, especially cues arising from the behavior of other persons. The accuracy with which a person notices such cues and draws conclusions regarding the role of the other is directly related to the accuracy with which he locates himself in the reciprocal or complementary role. The validity, propriety, and convincingness of his role enactment, then, depends on how accurately he perceives the role of the other. [See PERCEPTION, articles on PERSON PERCEPTION and SOCIAL PERCEPTION.]

**Role demands.** Once a person correctly locates the position of the other on the basis of cues emitted by the other interactant, the possible choice of role behaviors is reduced from near-infinity to a small number. Further constraints on the choice of role behaviors are introduced when certain additional features of the situation are taken into account. These may be called role demands, that is, demands for a specific role enactment.

Silently operating to guide the actor in his choice of roles, these demands stem from cultural norms and may, in fact, dictate a role choice that is contradictory to requirements under conditions when the demands are not operative. Among such demands one may list norms for modesty, communication, control of aggression, cooperation, face-saving, public commitment, and prevention of embarrassment to others. Violation of such norms ordinarily carries heavy sanctions against the violator, hence their power to constrain the choice of role behavior.

Two series of experiments by Orne (1959) illustrate in a striking way the necessity of taking into account the role demand variable, or, to use his designation, the demand character of the environment. In his first series of studies he demonstrated that the role enactments of subjects properly motivated to simulate hypnotic subjects could not be differentiated from the role enactments of subjects who were instructed through traditional

hypnotic procedures. By experimentally manipulating the role demands of the simulators, he approximated the demand character of the situation of the genuine hypnotic subjects. His simulators were instructed by an associate to pretend to be hypnotized and to try to deceive an expert in hypnotism. This study, together with a series of studies reported by Sarbin (1950), raises the possibility that hypnotic behavior is role enactment and that the manipulated demand for a specific role enactment is in large measure responsible for the outcome. One of the demands used by professional entertainers who perform hypnosis is that embarrassment to the other, in this case the hypnotist, be prevented. In a public setting the subject is in a position to embarrass the hypnotist by rejecting his instructions. However, for most persons the prevention of embarrassment is a powerful norm, and the informed hypnotist will capitalize on this fact.

Orne's second series of studies (Orne & Scheibe 1964) is addressed to the social aspects of the psychological experiment. Generalizing from the effects of manipulating role demands in the hypnosis experiment, he hypothesized that the outcomes in psychological research might also be related to implicit or explicit demands. Such demands operate when a subject wittingly or unwittingly learns that he is in the experimental group or in the control group. The experiment was conducted in a laboratory setting that simulated sensory deprivation experiments, with an examination by a white-coated physician and the presence of a panic button in the experimental room, but without actual sensory deprivation. The experimental subjects reported many, if not all, of the bizarre and extreme phenomena attributed to actual sensory deprivation. Subjects who were in the control condition received the same experimental treatment (without the panic button) and reported none of the sensory deprivation phenomena. In brief, different role demands led to different outcomes. In this experiment the assignment to experimental or control group was made explicit. In the usual psychological experiment the subject is left free to speculate on whether he is in the experimental or control group. He will use whatever inputs are available to help define his role. The outcome of his performance in the role of experimental subject will be influenced by his responsiveness to the intended or unintended role demands. [See HYPNOSIS; PERSUASION; SUGGESTION.]

**Role-taking aptitude.** Cameron (1947), Gough (1948), and Sarbin (1950), among others, have presented arguments for the existence of a skill,

aptitude, or competence that facilitates role enactment. Presumably acquired early in life through subtle learning experiences, this role-taking aptitude may be regarded as parallel to other aptitudes, such as mechanical, clerical, and drawing aptitudes. Authorities have not always been clear in their use of the term "role-taking aptitude"; in some contexts the referent is the ease with which a person enacts a number of roles, as in the case of the successful professional actor; in others the referent is the facility with which a person adopts and enacts a role on the basis of limited information. In the former referent the point of interest is role enactment as motoric (including gestural and verbal) behavior; in the latter it is cognitive and perceptual behavior.

Empirical studies have focused primarily on the cognitive component of this skill. With few exceptions, there has been no accurate measurement of the skill as a general cognitive competence. Most investigators, in fact, have drawn the conclusion that accuracy in predicting the behavior of others is a function of "stereotype accuracy"; i.e., the prediction is accurate insofar as the target person is regarded as an exemplar of a class of persons of known characteristics. If the subject knows the role system and the expectations that make up this system, he can extrapolate to any individual occupying a position in the system. The work of Gage (1953) is typical. Predictions of conduct were more accurate when based on general role expectations than on perceived idiosyncrasies of the target person. Although the experimental literature warns us to remain skeptical about a general role-taking aptitude, Cline and Richards (1960) appear to have demonstrated that such a disposition does exist. In a series of carefully controlled experiments some subjects made verifiable inferences about the social behavior of target persons after observing samples of behavior in sound motion pictures. The accuracy of these inferences could not be attributed to such conceptions as stereotype accuracy.

The motoric component has not been systematically studied except in the context of dramatic acting. Like the cognitive component, the motoric component of role-taking skill presupposes broad acquaintance with, and practice of, overt role behaviors associated with many positions. Although every person's repertory of verbal and gestural actions is different from every other's, a minimum of this skill is required for social interaction. Assessment of this variable can at present be achieved only through judgments made by observers. For example, Sarbin and Lim (1963) had their experi-

mental subjects perform pantomime improvisations before a panel of specialists in dramatic arts who recorded on a rating scale their impressions of the convincingness of the performance. The purpose of the experiment was to determine whether relative responsiveness in the hypnosis situation could be attributed to the motoric component of the role-taking skill. The findings clearly showed that part of the variation in hypnotic behavior can be attributed to the motoric role-taking skill. In earlier writings the role-taking skill was likened to empathy, or the ability to take the part of the other. The term implied that the actor would take the perspective of the target person, sharing not only his attitudes and beliefs but also his feelings.

Critics of role theory have pointed to the confidence man as a person who is gifted in taking the role of the other but who obviously does not genuinely share the perspective of the victim. This observation has been used to question the utility of the concept of role-taking aptitude. The criticism may be outlined somewhat as follows: If the confidence man really takes the role of the other, would he not then see himself as the victim, feel the pain of loss or embarrassment, and reverse his behavior? This criticism confuses two dimensions in the cognitive process. The first is the basis of knowledge of people in general, acquaintance with the class of persons of which the intended victim is a member, and study of the intended victim himself, the confidence man draws inferences about the probable role behavior of the victim, given certain role demands that the confidence man may manipulate. The second dimension is an evaluative one and has no necessary connection with the first. The value that one places on his own conduct need bear no more relation to his skill in role taking than to any other skill.

**Self-role congruence.** The writings of George H. Mead contain observations and speculations about two conceptions that have become thoroughly entrenched in modern psychology, role and self. The extensions of role have already been discussed. For a more complete analysis of the variation in effectiveness of role enactment, the concept of self must be invoked. However, it does not stand alone but must be regarded as one of a set of conceptions—this set describable on a dimension of congruence or compatibility. The belief that a role is performed better if its requirements are consonant with one's "natural inclinations" comes to us from folk psychology. By translating "natural inclinations" to self concept, or self characteristics, the

folk belief can be translated into a scientifically testable hypothesis, namely, that the effectiveness or validity of role enactment is related to the degree of congruence of self and role.

In brief, the self may be defined as the residues of a human being's transactions with objects and events, including other people. These residues are the referents for the symbol *I* (Sarbin 1954). To assess self structures, a large number of procedures have been devised, including autobiographies, speech and handwriting samples, responses to unstructured inkblots, endorsements of personality test items, and adjective check lists. In our linguistic system the most frequently used device for talking about self characteristics is the adjective. A person can describe his self as a catalogue of traits through the use of lists of adjectives, such as friendly, quiet, calm, vain, confident. The adjective check list, widely used in research settings, is based on this observation. Another widely used procedure in contemporary psychology is the personality inventory. This instrument is made up of incomplete *I*-statements requiring the respondent to indicate various predicates with himself as the subject, in this way expressing his preferences, attitudes, feelings, beliefs, values, and/or opinions. The dimensions used for organizing such sentences into scales are constructed for particular purposes by the investigator or distilled through analytic and statistical procedures. [See PERSONALITY MEASUREMENT, article on PERSONALITY INVENTORIES; SELF CONCEPT.]

Through the use of adjective check lists and inventories of *I*-statements one can systematically specify the qualitative requirements of a role (for example, a club treasurer must be honest and efficient) and compare such requirements with the self characteristics of persons who are assigned the role (for example, George sees himself as honest and efficient). When self and role characteristics are congruent, a convincing performance is expected, other things being equal. When self and role characteristics are incongruent or antagonistic, the enactment is likely to be invalid and unconvincing.

A study reported by Smelser (1961) illustrates the use of the variable of self-role congruence. Two samples of experimental subjects were selected, the members of one group having high scores on the trait "dominance," derived from the California Psychological Inventory, the members of the second having low scores (see Gough 1957). The subjects, in pairs, were placed in a cooperative work situation and were systematically assigned

roles calling for dominant or submissive enactments. The most productive pairs were those where dominant subjects had been assigned the dominant role and nondominant subjects the submissive role. The least productive pairs were those where the self characteristics and role characteristics had been reversed.

Employment of the self-role congruence variable has been especially useful in predicting effective enactment in the hypnosis role. Sarbin and Andersen (1964) have reported experiments whose results could be interpreted as showing that persons whose self characteristics are similar to the requirements of the role of hypnosis subject enact that role with greater convincingness. Their procedure involved the construction of an inventory of I-statements whose items reflected the kinds of role behaviors traditionally associated with hypnosis. Two of the dimensions of the role are (1) to become absorbed, to concentrate, and (2) to accept readily altered attentional and mood experiences. Illustrative of the I-statements written to tap corresponding self characteristics are the following statements: "I sometimes become so absorbed in a task that I am forgetful of other, less important aspects of the daily routine"; "I would not be afraid of anything that would temporarily change my awareness of my surroundings." The study yielded significant correlations between scores on the self-assessment inventory and the degree of convincingness in the enactment of the role.

An alternate way of regarding this variable is available. Where the self becomes involved in the role, the enactment is more likely to be judged as valid, convincing, and proper. It has been suggested that forced compliance to a role whose requirements are incompatible with one's self characteristics will not produce changes in the self. For example, attempts to indoctrinate prisoners of war in alien ideology generally fail because of lack of self-involvement in the role, even though the prisoners may give the appearance of involvement through the use of histrionic talents. [See BRAIN-WASHING.]

**Reinforcement properties of the audience.** Unlike many current attempts to understand social psychological phenomena, role theory addresses itself to *continuities* in conduct rather than to small samples of outcome behaviors. Social roles are enacted over time: the performances are protracted. To employ the dramaturgical metaphor further, roles are enacted before audiences—sometimes a one-person audience, as in psychoanalytic therapy;

sometimes a small group audience, as in a work or discussion group; sometimes a large mass audience, as at political meetings, the theater, and professional football games; and sometimes a symbolic audience, as in a writer's imagined picture of his reading audience. Audiences may serve two functions, providing cues helpful to the actor in locating his role and providing social reinforcements or sanctions. The plethora of studies on operant conditioning may be taken as a paradigm for the reinforcement properties of the audience (Krasner & Ullman 1965). In operant conditioning, selected responses of the subject are reinforced through social reinforcements, such as approval, praise, eye contact, friendly gesture, and nodding, or through more direct reinforcements, such as food and money. In the usual case of social interaction, audiences primarily provide social reinforcements. The effect of positive reinforcements, other things being equal, is to encourage the actor to continue his performance and to think that it is convincing, valid, and proper. Negative reinforcements, on the other hand, communicate to the actor that his role enactment is invalid and discourages the continuation of the role. [See COMMUNICATION, MASS, especially the article on AUDIENCES; LEARNING, articles on INSTRUMENTAL LEARNING and REINFORCEMENT.]

This article has attempted to identify current conceptions that may be organized under the general heading of role theory. The outcome variable of interest to psychologists whose work is guided by this orientation is *role enactment*, that is, the overt conduct of a person in his effort to validate the occupancy of the positions to which he is assigned in various macrostructures and microstructures. Role enactments are judged by audiences along various dimensions, in general reflecting the convincingness, propriety, effectiveness, or validity of the enactment. Because role enactments vary in these dimensions, investigators have attempted to isolate and identify the sources of variation. Six components of effective role enactment have been described and at least one empirical study introduced to illustrate the utility of each variable. The validity, effectiveness, or convincingness of role enactment depends on (1) a valid set of role expectations, (2) an accurate assessment of the role of the other (and reciprocally the self), (3) sensitivity to the role demands of the situation, (4) role-relevant cognitive and motoric aptitudes, (5) self characteristics congruent with the role, and (6) positive reinforcements for appropriate

acts. The six variables are listed as if they were independent of one another. As yet they can be designated only as conceptually independent; further research will tell to what extent they are empirically independent—and under what conditions.

#### II

#### SOCIOLOGICAL ASPECTS

The concept of *role*, borrowed from the stage, has been central in those sociological analyses which seek to link the functioning of the social order with the characteristics and behavior of the individuals who make it up. The concept has a relatively long history in American sociology and has attracted interest from some of its best minds. For instance, Park (1926, p. 137) noted that "everyone is always and everywhere, more or less consciously, playing a role. . . . It is in these roles that we know each other; it is in these roles that we know ourselves." In this and most subsequent usages, the following elements appear in the definition of role: it provides a comprehensive *pattern* for behavior and attitudes; it constitutes a *strategy* for coping with a recurrent type of situation; it is *socially identified*, more or less clearly, as an entity; it is subject to being played recognizably by *different individuals*; and it supplies a major basis for *identifying* and *placing* persons in society.

George H. Mead's observation (1934) that in mature social behavior the individual works out his own role by imaginatively taking the role of the other soon led to the idea that articulation between the roles played by partners in interaction determines whether interaction is harmonious and productive. The theme that personal and social disorganization arises from failure of the individual to choose between incompatible roles was developed by Mowrer (1935), and the problem of balancing rights and obligations in role articulation was explored by Kirkpatrick (1936). In the same year, Linton (1936) presented the first systematic statement identifying role as a *segment of culture*; he held that it consisted of behavioral prescriptions or norms bearing one-to-one correspondence with social status [see STATUS, SOCIAL; the biography of LINTON]. All these traditions have inspired descrip-

tive studies, stressing personal and organizational strains from incomplete articulation of roles.

More recently such topics as the spontaneous emergence of similar informal roles in different discussion groups (Benne & Sheats 1948) and the hypothesis of role specialization in task and social-emotional behavior (Bales 1950) have been the subject of experimental study. Many organizational studies have demonstrated that lack of clarity and consensus in role conceptions is a factor in reducing organizational effectiveness and morale (see, for instance, Gross et al. 1958). One serious effort has been made to review and appraise this body of literature comprehensively (Rocheblave-Spenlé 1962).

This variety of studies is an index of some major differences in usage. A few writers equate "role" with the actual *behavior* of an individual, although most distinguish between role as expected behavior or conceptions and role behavior as enactment. Furthermore, there is a continuing issue of generality, raised by Linton's restriction of role to the prescriptions associated with a status (1936). Another influence is that of behaviorism, which led to an effort to think of a role as an inventory of specific behaviors or conditioned responses (Cottrell 1942), rather than as certain purposes, sentiments, and strategies in the context of which both routinized and improvised behavior are mixed. Authorities also differ on whether "role" should be said to consist only of the *norms* applicable to a position or should include not only norms but also expectations and conceptions with respect to behaviors that are only in the faintest degree normative. Finally, role is defined by some as essentially a part to be learned and played, whereas for others it is primarily a way of coping with an imputed other-role.

### Emergence of roles

Despite definitional differences, it is possible to state, as a series of rough "postulates," the tendencies that are usually assumed to constitute the normal role processes. Role theory will first be considered as it would apply to a self-contained, dynamic system of interacting roles; considerations of organizational and societal setting, as well as of individual personality, will be discussed later.

**Role differentiation and accretion.** In any interactive situation, behavior, sentiments, and motives tend to be differentiated into units, which can be called roles; once roles are differentiated, elements of behavior, sentiment, and motives that appear in the same situation tend to be assigned to the existing roles. This postulate suggests that one should

study degrees of differentiation, as indicated by *clarity* of role definition and degree of *role overlap*. The hypothesis has been widely accepted that individual adjustment to role and group effectiveness is positively related to clarity and negatively related to overlap, although excessive clarity may be overly restrictive to the individual and rigidifying to the organization, and some overlap may facilitate empathic understanding and contribute to interpersonal bonds. The postulate also suggests that attention should be given to what is grouped and what is separated into different roles. Internal consistency of roles is thought to facilitate individual adjustment and group efficiency; internal contradiction is held to be explained with the help of such concepts as role set (discussed below), culture contact and assimilation, imposition of role structure by authority, and rigidification through formalization and tradition. Feasibility of enactment by a single individual has been the most common principle invoked to explain the peculiar way in which the content of one role can be separated from that of another; additional principles, such as those arising from the functional requirements of the group, are noted below.

**Meaningfulness.** In any interactive situation the meaning of individual actions for ego (the actor) and for any alters (partners in interaction) is assigned on the basis of the imputed role. This postulate is inspired by the common observation that identical actions mean totally different things when viewed as expressions of different roles.

**Behavioral correspondence.** A tendency (never completely realized) for the social character of a role to shift toward correspondence with patterns of behavior is actually seen to take place within the role context. For example, changes in the wife and mother role have been attributed to removal of many traditional domestic activities from the home, despite inertial factors that caused a lag in the adaptation.

**Evaluation.** Every role tends to acquire an evaluation, both in terms of rank and in terms of its socially favorable or detrimental character. The perceived utility of the role, the power resident in the role, and association of the role with other valued roles are among hypothesized determinants of role evaluation.

### Role as interactive framework

**Interaction.** The establishment and persistence of interaction tend to depend on the emergence and identification of ego and alter roles. This postulate extends the meaningfulness postulate to

interaction. Identifications are tentative and are based on cues, so the character of interaction in any initial encounter, or under grossly changed conditions, is tentative and changeable.

**Role complementarity.** Each role tends to form as a comprehensive way of coping with one or more relevant alter roles. The actual character of any given role involves a constant strain toward equilibrium between actual behavior, evaluative adjustments between roles, and the tension of maintaining each as a viable role in relation to the other. For example, in any role relationship of superordination-subordination, such as parent-child, teacher-student, master-servant, policeman-criminal, the subordinate role will incorporate mechanisms that afford some latitude for action.

**Role consensus.** There is a tendency toward consensus regarding the content of roles in interaction. Because of the adaptation that takes place as roles form, some consensus regarding what enactors of each role are to do seems inevitable, although the degree of consensus required for a viable interaction system is not great. Role dissensus has generally been thought an obstacle to harmonious interaction (as in the family), although the evidence is not entirely consistent.

**Legitimate expectation.** There is a tendency for stabilized roles to be assigned the character of legitimate expectations, implying that deviation from expectation is a breach of rules or violation of trust. Willard Waller's observations (1938) about the sense of injustice that arises in married life when one partner deviates from what has come to be the customary pattern of behavior suggest the following hypothesis: the degree to which ego ascribes legitimacy to his expectations for alter's role varies directly with the degree to which the selection and enactment of his role depend on alter's role and role behavior. The evaluation of the role also appears to make a difference, suggesting this principle: to the extent to which alter's role is positively valued with respect to rank and favorableness, ego will translate his anticipations regarding alter's role into legitimate expectations. Thus an unfavorably evaluated role, such as criminal or indigent, evokes legitimate expectations of continuance in the role only to the extent of justifying adaptive behavior by relevant others, such as surveillance by police and anticipatory defensive behavior.

### **Role and actor**

**Role persistence.** Once stabilized, the role structure tends to persist, regardless of changes in the

actors. This postulate takes two specific forms. First, when an actor leaves the group and is replaced by another, there is a tendency to allocate to the new member the role played by the one who leaves. Second, if one actor changes roles, there is a tendency for another actor to make a compensatory change of roles in order to maintain the original role structure. The latter principle has been referred to as role appropriation by Perry, Silber, and Bloch (1956), who noted that in some families, when the parent became disorganized and assumed a childlike role of dependence in a disaster situation, a child suddenly blossomed into responsibility and helped to supply family leadership.

**Role allocation.** There is a tendency for a given individual to be identified with a given role, and a complementary tendency for an individual to adopt a given role, for the duration of the interaction. The postulate of role allocation, in combination with the meaningfulness postulate, suggests that an actor's behavior is without clear meaning until he settles on a particular role in interaction. In combination with the postulate of legitimate expectation, role allocation suggests that an individual whose behavior cannot be fitted into an identifiable role will be regarded as violating the terms of interaction.

A role allocation has taken place when relevant alters interact with ego on the basis of the same role as he is playing. Ego's act of attempting to determine the role that alter will play has been dubbed "altercasting" by Weinstein and Deutschberger (1963). The alter's use of a relatively unambiguous response to confer the right to play the chosen role is sometimes designated as *validation*.

The bases for role allocation can be inferred from the postulate of evaluation in conjunction with the postulate of role complementarity (see above). Since roles are evaluated, there is likely to be competition for the preferred roles, and the principles of any competitive situation will be at work. Because of complementarity of roles, it is essential that an individual be able to play the role with sufficient adequacy; demonstrated adequacy or inadequacy therefore affects the willingness of others to allocate to him a particular role.

**Role taking.** To the extent to which ego's role is an adaptation to alter's role, it incorporates some conception of alter's role. If the actor is guided chiefly by his conception of alter's role (role taking), his behavior has an element of improvisation about it; he simply follows the course of action that seems reasonable for coping with alter under

the circumstances. A further implication of the role-taking postulate is that the individual learns roles in pairs or sets, not singly.

**Role adequacy.** Role behavior tends to be judged as "adequate" or "inadequate" by comparison with some definite conception of the role in question. When combined with the role allocation postulate, this observation leads to the following generalization: to the degree to which a role is favorably evaluated, judgments of role adequacy tend to be translated into evaluations of the person playing the role.

**Role reciprocity.** The degree of role adequacy legitimately expected of ego tends to be a function of the degree of role adequacy attributed to alter. Conversely, the degree to which ego can legitimately claim the privileges of his role tends to be a function of his degree of role adequacy. With this postulate, which has been elaborated by Gouldner (1960), we call attention to two facts, namely, that role behavior does not normally correspond precisely with role conceptions, and that legitimate expectations are adjusted in the course of interaction.

### Organizational setting

The organizational setting supplies both direction and constraint to the working of the processes already outlined, thus bringing them into more complex interrelationships.

**Organizational goal dominance.** To the extent to which roles are incorporated into an organizational setting, organizational goals tend to become the crucial criteria for role differentiation, evaluation, complementarity, legitimacy of expectation, consensus, allocation, and judgments of adequacy. To the extent to which the organization has well-defined goals, the most salient role differentiation will be according to different kinds of tasks that together accomplish the goal. The expectations assigned greatest legitimacy and held with most consensus will tend, under these circumstances, to be those with most obvious task relevance; judgments of role adequacy will therefore weigh task adequacy more heavily than other aspects of role adequacy.

**Legitimate role definers.** To the extent to which roles are incorporated into an organizational setting, the rights to define the legitimate character of roles, to set the evaluations on roles, to allocate roles, and to judge role adequacy tend to be lodged in particular roles.

**Status.** To the extent to which roles are incorporated into an organizational setting, role differ-

entiation tends to link roles to statuses in the organization.

**Role set.** To the extent to which roles are incorporated into an organizational setting, each tends to develop as a pattern of adaptation to multiple alter roles. The teacher role must incorporate tenable adaptations to pupils, parents, other teachers, and principals, as well as to less salient alters. Discrepant expectations may arise from relations with each of the alters; Merton (1957) describes several mechanisms that are employed to minimize the conflict in the role set.

**Formalization.** To the extent to which roles are incorporated into an organizational setting, their persistence is intensified through tradition and formalization. A strain then develops between formalized or traditional role definitions and the informal role structure.

### Societal setting

Because society is built on accommodation among many organizations, it introduces multiple organizational referents for roles and multiple roles for the actor.

**Economy of roles.** Similar roles in different contexts tend to become merged, so as to be identified as a single role recurring in different relationships. As a corollary, roles in situations of limited generality and social significance tend to be shaped in accordance with the pattern of roles in situations of greater generality and social significance. One index of this tendency is that we often speak of male and female roles, of heroic and unheroic roles, of judge and defendant, when seeking meaning and order in quite simple interaction.

**Value anchorage.** To the extent to which roles are referred to a societal context, differentiation tends to link roles to social values. Status is not thereby made less important as a point of anchorage, but social values take the place of organizational goals as major anchorages for roles. Values thus supply one of the major bases for the simplification of an otherwise unmanageable profusion of recognized roles in society; even in more limited contexts, as we have seen in the discussion of role economy, roles for interaction tend to be fitted into a framework of social values.

**Allocation consistency.** The individual in society tends to be assigned and to assume roles that are consistent with one another. The role conflict which arises from failure of this process has been subject to considerable study. Mechanisms such as organizational compartmentalization facilitate the tendency; there are also various recognized transi-

tional cues, as when a functionary who wishes to pass from one role to another speaks of "putting on a different hat." Perhaps the most specific mechanism for achieving consistency is the tendency for roles that have the greatest generality, such as age, sex, and occupation, to serve as qualifying criteria for the allocation of other roles.

### Role and person

When we turn to the consequences of role process for the individual as a sociological entity, we look at the *actor* in relation to a role-in-situation, and we observe the *person* in the setting of society. For the actor the primary concern is coping with strain; for the person the dynamics hinge on the management of the several roles in his repertoire.

**Role strain.** The actor tends to act so as to alleviate role strain arising from role contradiction, role conflict, and role inadequacy and to heighten the gratifications of high role adequacy. Role strain comes largely from failure of the many processes already outlined to function adequately, so as to leave unclear, incomplete, and contradictory elements in a role. This may come about through failure of role cues, gross lack of role consensus, and so forth. Little has been noted that is distinctive about adjustments to role strain, as compared to ways of coping with any other type of stress.

**Socialization.** The individual in society tends to adopt a repertoire of role relationships as a framework for his own behavior and as a perspective for the interpretation of the behavior of others. It is important to remember that socialization is partly a matter of learning somewhat culturally standardized role conceptions and partly a matter of acquiring a viable image of the social world by means of the tentative and adaptive processes that make up role enactment.

**Self-conception.** The individual tends to form a self-conception by selective identification of certain roles as more characteristically himself than other roles in his repertoire. The self-conception, from a sociological point of view, is not a set of traits but an organization of roles that both articulates the person with the society and incorporates role evaluations. On the basis of the roles included, the individual is said to develop a sense of personal prestige, which is likely to be reflected in his bearing, his self-assurance, and other aspects of his interpersonal relations. On the basis of his perceptions of role adequacy in these most "ego-involved" roles (Sherif & Cantril 1947), the individual develops a self-esteem.

**Adaptivity of self-conception.** The self-conception tends to stress those roles which supply the

basis for effective adaptation to relevant alters. Thus, while there is no simple or uniform self-conception held by all persons defined by society as "criminal," the established criminal must somehow take account, in his self-conception, of the fact that his criminal identification is recurrently the most salient consideration shaping the behavior of others toward him in a variety of situations.

**Role distance.** To the extent to which the person must play roles that contradict his self-conception, these roles will be assigned "role distance," together with mechanisms for demonstrating the lack of personal involvement that the person feels when playing these roles (Goffman 1961).

## RORSCHACH, HERMANN

Hermann Rorschach, Swiss psychologist, was born in 1884 and died in 1922. These were the exciting years when psychoanalysis came of age and gave impetus to fresh inquiry in all social and cultural areas. In the psychology of the individual, psychoanalysis revealed hitherto unfathomed aspects of the emotions. Scientific psychology was thus faced with a new challenge, the measurement of unconscious emotions. Rorschach's famous test met this newly felt need.

Rorschach, the first of three children, was born in Zurich. When he was two years old the family moved to Schaffhausen, a commercially busy and culturally stimulating city; his father became a drawing teacher there. His mother died when he was 12 and his father when he was 18. In his final year in the *Kantonschule*, undecided whether to choose a career in science or art, he wrote to the biologist Ernst Haeckel (O. Rorschach 1944; Morgenthauer 1921), who advised him to go into medicine. He began his studies in Zurich and went successively to Berlin, to Bonn, then back to the University of Zurich, where he took his degree in 1912. His dissertation on hallucinations forecast his interest in psychopathology. The research was done under Eugen Bleuler's supervision.

In 1910 Rorschach married Olga Stemplin, a Russian, who surely had something to do with his decision, in 1913, to take a post in a sanitarium near Moscow. It was his third journey to Russia, and Olga Rorschach has described (1944) his favorable reaction to the vastness of that country, to its people, its churches, and its landscape. He had learned Russian, and he wrote a novel (unpublished) about Pushkin and later planned a work on Dostoevski. After less than a year in Russia, he returned to Switzerland. He had held posts in three mental hospitals when he was appointed as assistant director in the cantonal institute in Herisau, and he remained in this position until he died of acute peritonitis in 1922. His one important professional office was that of vice-president, in 1919, of the then newly organized Swiss Psychoanalytic Society; Emil Oberholzer was the president. Some correspondence with Morgenthauer (1965) shows how strenuously Rorschach promoted psychoanalysis in Swiss medical circles.

Rorschach was undoubtedly supported in his psychoanalytic orientation by Bleuler, who was among the first to receive Freud's ideas sympathetically. Jung, a resident in a suburb of Zurich, was giving impetus to experimentation with free association as well as to extraversion-introversion theory. Bleuler's psychiatry and the theories of Jung and Freud were the three principal sources of the ideas that were to crystallize in Rorschach's test. He used psychoanalytic theory in interpreting the test record of one of Oberholzer's patients (Rorschach & Oberholzer 1923) and also in an article on two Swiss leaders of religious sects (1927), whom he had studied before he developed the test. In this paper he traced personality changes from the introverted to the extraverted type. He anticipated his own exposition in the *Psychodiagnostics* ([1921] 1942, pp. 102 ff.).

Rorschach's test clearly reflects his particular scientific preferences, powerful as the influences of Freud, Jung, and Bleuler may have been. His basic method was empirical and his temperament that of the experimentalist. Rorschach himself so described his work in the brief foreword to the *Psychodiagnostics*: "The entire work is predominantly empirical in character" (1921). He offered suggestions for controlled experiments, especially with regard to those two critical variables—color, indicative of acted out feelings, and movement, indicative of ideas lived in the imagination, such as wish fulfillments or daydreams ([1921] 1942, p. 58). They are the main ingredients of his *Erlebnistypus*, the core of his personality concept. The ratio between the number of movement responses and the weighted value of color responses is an index of the *Erlebnistypus*. The ratio can change, as can also the *Erlebnistypus*, with the increase or reduction of either color or movement responses.

Rorschach's broad psychological interests are reflected in his penetrating studies of some Swiss religious sects. According to Morgenthaler (1965), he was striving for a synthesis of folkways, ethnology, religion, and psychopathology in a single sociological system. Some of his most important work was done on schizophrenia.

It is intriguing to apply his personality theories to what is known of Rorschach himself. Warmth of feeling for others was one of his traits, one that he acquired chiefly from his mother, a kindly and sociable person (Ellenberger 1954). To his father he owed his aptitude for drawing, and he encouraged his patients to draw. He had many acquaintances but only a few intimate friends. According to his own *Erlebnistypus* concept, he would thus be introversion. However, Olga Rorschach writes, "He was constantly growing, ever expanding his *Erlebnistypus*, from introversion towards extraversion. He thus attained to an enviable ambiequality" (1944). And she quotes Rorschach as saying that "the ideal is the ambiequal."

Rorschach was a venturesome explorer, and in that most taxing terrain, the human personality. While he clung to the observable, he arrived at his conclusions more by his insights than by the logic of statistics. His short life did not permit him to complete his work. But as a tool for clinical exploration as well as for general research in personality, Rorschach's test has gone far toward meeting the challenge faced by a science of psychology.

#### ROSCHER, WILHELM

Wilhelm Georg Friedrich Roscher (1817-1894), German economist, was a descendant of an old Hanoverian family of officials and judges. He studied history and political science at Göttingen and Berlin. In 1840 he became a lecturer in both these subjects at the University of Göttingen, where in 1843 he rose to the rank of professor-extraordinary (comparable to associate professor), and the following year to full professor. In 1848 he was called to the University of Leipzig, where he remained until his death.

Roscher is commonly considered, with Karl Knies and Bruno Hildebrand, to be one of the founders of the "older historical school" of German economics. In his small book *Grundriss zu Vorlesungen über die Staatswirtschaft nach geschichtlicher Methode* (1843) he based the study of political economy on the principles of historical investigation. He was one of the first economists

other than Friedrich List to have done so; although in France Auguste Comte had argued in his *Cours de philosophie positive*, 1830–1842, that the historical method should be applied to all the social sciences, he had himself concentrated on sociology.

The *Grundriss* was the basis for Roscher's widely read *System der Volkswirtschaft*, a work of five volumes published between 1854 and 1894 and described in its subtitle as a handbook and reader for businessmen and students. It became the most influential textbook of political economy in Germany in the second half of the nineteenth century. Roscher also wrote some purely historical and philosophical books and articles in his early years, some political treatises, and many studies in the history of economic literature. His only work of lasting significance, however, is his *Geschichte der National-oekonomik in Deutschland* (1874).

Roscher called his method "historical" or "historico-physiological," in contrast to the "philosophical" or "idealistic" method. He contended that the object of political economy is not to establish the best possible state of things, but to describe the actual state at which the economy has arrived through continual development. Of the two crucial questions, "What is?" (positive economics) and "What ought to be?" (normative economics), Roscher wanted to answer only the former; the latter question, in his view, could not be studied scientifically because it depends on constantly changing opinions and individual choices. While a science could never be based on the German idealistic philosophy, the study of what actually occurred could provide a "firm island of scientific truth which may be accepted in the same manner as the adherents of different systems of medicine all admit the teaching of mathematical physics." ([1854–1894] 1901–1922, vol. 1, p. 80).

Compared to the "younger historical school," led by Gustav Schmoller, Roscher was much closer to the classical theory of economics. In contrast to List, whose focus was on the productive forces of every nation and who was therefore interested only in the dynamics of development, Roscher accepted the value theory of the classical school for the analysis of any given stage of the economy and conceived of a process of organic development taking place between statically conceived stages. He thought that the life of nations, like the vegetable and animal world, has four such stages of development: childhood, youth, manhood, and old age. Thus, development is in both an ascending and a descending direction (in contrast to List's theory that evolution is exclusively ascending).

Roscher believed that development could best be

studied by inquiring into the history of ancient nations like Greece and Rome, because that history has been terminated. Three factors of production govern the evolution of every nation: land, labor, and capital. Of these, one is always predominant in each successive stage of life. A close, and especially a statistical, knowledge of economic facts, according to the "objectivist" spirit of Leopold von Ranke, would permit, in Roscher's view, the solution of conflicts of interest between the factors of production. Roscher was much more skilled in collecting obscure details and understanding particular events and theories than in formulating a theory of his own. Lacking any systematic theory, he was not forced to come to terms with the historical facts he collected or to recognize the futility of his search for "laws of nature" or "laws of evolution."

Roscher could not fulfill the declared aim of his historical approach: to achieve for political economy what the historical approach of F. K. von Savigny and Karl F. Eichhorn had already achieved for the field of law and legislation. However, his *Geschichte der National-oekonomik in Deutschland* remains an outstanding work that must be consulted by everyone who does research in that field. Roscher was interested not only in the history of economic analysis but also in the personality of every economist and in the character of every economic work. His book is, therefore, a compendium, perhaps even an encyclopedia, of the history of German economists and of German economic and economic-political literature up to 1874.

### ROSS, EDWARD A.

Edward Alsworth Ross (1866-1951) was one of the founders of American sociology and is perhaps best remembered for his militant advocacy of melioristic sociology—a sociology dedicated to the cause of social reform. He was internationally known, also, as a sociological theorist.

Born of Scotch-Irish parents in Illinois, Ross grew up on the Middle Border: as a child, he was taken to Centralia, Kansas, and then to Cedar Rapids, Iowa. Orphaned when he was not yet ten years old, he was cared for by various relatives in Iowa and finally given a foster home with the Beach family in Marion, Iowa; he maintained close ties with Mrs. Beach until her death. At the age of 16 Ross left Marion to study at the preparatory school of Coe College, and 4½ years later he received his B.A. from that institution. Following his graduation, he studied in Germany and at Johns Hopkins, where he received his Ph.D. in 1891. After teaching for one year at Indiana University and then at Cornell, Ross joined the faculty at Stanford University in 1893 as a full professor of administration and finance.

Ross's fervent Populist-Progressive views on controversial social issues soon aroused the wrath of California conservatives. Mrs. Leland Stanford, the widow of the founder of Stanford University, repeatedly urged David Starr Jordan, the president of that university, to dismiss Ross; Jordan interceded for Ross on several occasions but was finally forced to demand his resignation. In November 1900 Ross accompanied his enforced resignation with a public statement blaming Mrs. Stanford for

his ouster. Seven of his colleagues subsequently resigned in sympathy or were similarly dismissed. Throughout the country, Ross's dismissal became a *cause célèbre*. Public figures and publicists censured the university for dismissing a scholar because of his political views, and Ross, in the role of martyr, encouraged the public outcry. He continued his academic career first at the University of Nebraska and then, in 1906, at the University of Wisconsin, where he taught until his retirement in 1937.

The sources of the various components of Ross's thought, of his sociology, his Progressivism, and his intermittent nativism, are to be found in the social and economic tensions of a predominantly agrarian society in the process of urbanization. Reared as he had been in the moralistic Middle West, Ross's response to this disruptive transformation was to seek to retain the values of nineteenth-century America: the dignity of the individual, personal and public morality, and the continuing progress of man and society. The virtues of the past would survive if public opinion were guided by enlightened leaders, if legal sanctions were applied in a sophisticated manner, and if supernatural religion were abandoned. Thus Ross sought to synthesize the old and the new, to infuse an impersonal industrial society with the idealized virtues of the face-to-face community in which he grew up.

Ross's important contributions to American sociology came early in his career. His sociological theory was allied to his ideology: in his *Foundations of Sociology* (1897-1904), a collection of essays, he attacked conservative social Darwinism and tried instead to fashion a sociological theory that could be used to understand and reform American society. He applied his erudition to the demolition of such outmoded theories as the monism of Buckle, Loria, and Vico; the bio-organicism of von Lillienfeld and Schäffle; the genetic evolutionism of DeGreef and L. H. Morgan; and, with particular determination, he assaulted the mechanistic theory of Herbert Spencer. Ross did accept two basic nineteenth-century concepts: organicism and positivism. However, he altered organicism by stripping it of its biological and physical implications and redefining it in social and psychological terms. He refocused the positivist approach on the study of social phenomena in small units, as the necessary basis for a valid science of society. If Ross did not succeed in making organicism completely social or positivism completely operational, he must nevertheless be credited with communicating the need for a new definition of the subject matter and methodology of sociology.

*Foundations* was an important work not only because it presented this new definition but also because it was the first book in American sociology to stress the importance of social processes as a sociological concept. Ross divided the social processes—the general and recurring phenomena that pervade the entire social order—into major categories and subcategories. In 1905, he described 11 major categories (for example, cooperation and competition) and 32 subcategories; by 1920, he had reduced the major divisions to four (association, domination, exploitation, and opposition). However, Ross never arrived at a definitive number of processes, nor did he ever establish the exact nomenclature to describe them. He saw these processes as accounting for such phenomena as the power of the army, the structure of the family, the functioning of the church, and the nature of the government. The analysis of social processes constituted the core of the textbooks he wrote between 1920 and 1940, and he utilized them to explain the civilizations of the past as well as contemporary society: war, for example, is the product of “competition,” slavery the result of “segregation” and “subordination,” and democracy the consequence of “equalization.”

Ross's sociological formalism—evidenced by his study of social processes—was supplemented by research on social behavior. *Social Control* (1901) and *Social Psychology* (1908) delineated the formal and informal ways in which society constrains the behavior of the individual. *Social Control* contained Ross's finest contribution to sociological thought and brought him international fame. Like William Graham Sumner's *Folkways* (1906) and Charles Horton Cooley's *Human Nature and the Social Order* (1902), *Social Control* was an attempt to explain order. Sumner understood social stability as the evolving “cultural system” produced by folkways and mores; Cooley stressed the role played by the subjective processes in the socialization of the individual (a “psychological system”) in creating stability. Taking a position between the two, Ross presented a “social system” that is both individualistic and interactional in that it integrates to some degree the external norms emphasized by Sumner and the inward processes discussed by Cooley. In addition to discussing the ways and means of societal control of the individual, Ross dealt with what he called the “grounds” of control, that is, the conditions for the need of social control, and with the relationship of social change to the techniques of control.

*Social Control* is still valuable as a listing of the means society has to control the individual: custom

and convention, legal and social sanction, religion and education. But the operation of social control is more complicated than it seemed to Ross in 1901. In his later years Ross recognized this and made an unsuccessful effort to remedy this failing; he never published this piece of work. He was unable to explain in a manner satisfactory to modern, predominantly interactionist, social psychologists the mechanism by which external norms (custom and convention, for example) are internalized.

Ross's *Social Psychology* (1908) is likewise obsolete. It was based on the Tardean imitation-suggestion theory and remained an academic best seller even when the Tardean theory itself was no longer accepted. Ross did not incorporate interactionist theories in his book, and this eventually led to its identification with an outmoded phase of social psychology that was concerned with mobs and panics, custom and convention. Nevertheless, *Social Psychology* served to stimulate an interest in that discipline and pointed to the need in the academic curriculum for the separate study of social psychology.

As a sociologist Ross faithfully served the cause of Progressivism, that outgrowth of the middle-class reform spirit which pervaded American life and thought in the first 15 years of the twentieth century. In *Foundations*, his definition of the social processes mirrors the temper and values of Progressive America. In *Social Control* and in *Social Psychology*, Ross was preoccupied with the problem that confronted all Progressives: the preservation of both individual freedom and social stability in a mass society. Ross did not see social stability threatened by the breakdown of social tradition and of supernatural religion, as did European social psychologists like Le Bon and Sighele. As a Progressive, he welcomed the dissolution of traditional institutions and rituals and even condoned an occasional mob action in the cause of social justice.

Throughout his career Ross was interested in practical reforms both at home and abroad, and his *Social Control* and *Social Psychology* are filled with specific suggestions for the mitigation of social evils. He did not hesitate to urge political leaders in foreign countries on every continent (he visited them all) to adopt American ways: to industrialize their economies and to democratize their political systems.

In addition to constructive Progressive ideas, a minor note of nativism was evident in Ross's thought for many decades. Until 1930 he was a spokesman for Anglo-Saxon superiority. His nativist syndrome included opposition to continued Japanese immigration to the United States in the

1890s and to southern and eastern European immigration in the early decades of the twentieth century, a preoccupation with eugenics, and an obsession with differential fertility rates. His nativism reveals his limited faith in the power of social institutions to cure social evils. Reform needed the reinforcement of nativism if the virtues of nineteenth-century rural American life were to be restored or perpetuated.

Ross was physically imposing (he was 6½ feet tall) and personally attractive. He could be both rigidly moral and shrewdly supple. He was generous but not effusive, frugal but not penurious. Despite his Stanford reputation and two subsequent incidents involving academic freedom at Wisconsin, he was far from seeking entanglement in controversies. He took a rather detached view of institutions and organizations, being reluctant either to exercise authority or to be dependent upon the authority of others. To be sure, he served two terms as president of the American Sociological Society (1914 and 1915) and was chairman of the sociology department at the University of Wisconsin from 1929 until 1937. With the exception of Lester F. Ward, whom Ross regarded intellectually and emotionally as a father figure, he rarely became involved in profound friendships or in taxing personal feuds, thus leaving himself free to pursue a productive as well as a lucrative career. (His introductory textbooks *The Principles of Sociology*, published in 1920, and *New-age Sociology*, published in 1940, were widely used.)

Ross is still a figure of consequence to his profession. As a reformer and, for a time, a creative social theorist, he deserves respect; as a writer and popularizer of sociology he has had few peers in the annals of American sociology.

JULIUS WEINBERG

[For the historical context of Ross's work, see SOCIAL DARWINISM and the biographies of COOLEY; LORIE; MORGAN, LEWIS HENRY; SPENCER; SUMNER; VICO; WARD, LESTER F. For discussion of the subsequent development of Ross's ideas, see SOCIAL CONTROL.]

#### WORKS BY ROSS

- (1897-1904) 1920 *Foundations of Sociology*. 5th ed. New York: Macmillan. → A collection of Ross's essays and lectures at the turn of the century; first published in book form in 1905. Especially valuable as a survey of contemporary sociological theory at an important juncture in the history of American sociology.
- (1901) 1928 *Social Control: A Survey of the Foundations of Order*. New York and London: Macmillan. → Dealing with the problem of how American mass society can achieve a balance between social stability and

individual freedom, this book represents Ross's most creative contribution to sociological thought.

- 1907 *Sin and Society: An Analysis of Latter-day Iniquity*. Boston: Houghton Mifflin. → A moralistic Progressive tract that makes a sophisticated plea for sociological jurisprudence—a demand that society bring its legal theory and practice abreast of current problems.
- (1908) 1918 *Social Psychology: An Outline and Source-book*. New York: Macmillan. → An exposition of Ross's Tardean imitation-suggestion theory and a primer in social psychology on which a generation of students was raised.
- (1909) 1919 *Changing America: Studies in Contemporary Society*. New York: Century. → A collection of Progressive pieces with popular appeal.
- 1919 *What Is America?* New York: Century. → Originally written for the U.S. government during World War I as a piece of "interpretation" (propaganda) to be used for overseas consumption and later converted by Ross for domestic readers. Extensively used in translation by foreign-language newspapers as part of the Americanization program after the war. An excellent summary of Ross's Progressive outlook on American history and society.
- (1920) 1938 *The Principles of Sociology*. 3d ed. New York: Century. → A mature presentation of Ross's sociological theory and findings. A highly readable text used for many years throughout the country.
- 1922 *The Social Trend*. New York: Century. → A collection of previously published essays and lectures on current popular issues.
- (1924-1927) 1928 *World Drift*. New York: Century. → An anthology of articles and addresses on foreign and domestic affairs.
- 1936 *Seventy Years of It: An Autobiography*. New York: Appleton. → Boastful and vain, yet an informative, revealing autobiography.
- 1940 *New-age Sociology*. New York and London: Appleton. → A further revision of the earlier texts and a not-too-successful attempt to keep data and theory abreast of current sociological thought.

## ROUSSEAU, JEAN JACQUES

In most of his writings, not merely in the *Contrat social*, Jean Jacques Rousseau (1712-1778) was obsessed by the demands of life in society, by the relationships of dependence and subordination which it creates among men, and by the rivalries and enmities which it engenders. Society, which should bring men together, in fact sets them apart and makes them enemies to their fellow men. Rousseau first became aware of this paradox not in terms of clearly conceived ideas but of deeply felt experience. In the course of a tormented and eventful life, he felt poignantly the injustice of a social order founded on the inequality of status and the impossibility of achieving happiness in such a society. To an unusual extent it is necessary to know about Rousseau's life in order to understand his work.

Early life. Rousseau was born in Geneva; although he spent the greater part of his life in France, he always felt himself to be a stranger there and made a great point of indicating his attachment for his "fatherland" by adding to his name the title "Citizen of Geneva."

It was in Geneva and in the surrounding countryside that his childhood years were spent. He never knew his mother, who died shortly after his birth, and, as he often noted, the education he received from his father was an unusual one. Isaac Rousseau was a capable watchmaker but an odd and temperamental man, and he all too early inculcated in his son a taste for reading by having him read novels and Plutarch's *Lives*. "When I was six," Rousseau wrote in a letter to Malesherbes, dated January 12, 1762, "I happened upon Plutarch; at eight I knew him by heart. I had read all the available novels, which had made me shed buckets of tears before the age when the heart usually takes an interest in such works. From them was formed in me that heroic and romantic taste which up to the present time has continued to grow, and which made me disgusted with everything except what resembled my follies" (*Oeuvres complètes*, vol. 1, p. 1134 in the Gallimard edition). Alluding to this reading, as well as to his precocious sensibility and troubling sensuality, Rousseau later wrote in the *Confessions*: "My childhood was not that of a child; my feelings and thoughts were always those of a man" (*ibid.*, p. 62).

At the age of 13, Rousseau was apprenticed to an engraver, who punished him harshly for petty thefts and pranks. After three years, a chance event, in which later he was to see a sign of des-

tiny, put an end to this apprenticeship and led to his departure from his native city. One Sunday in March 1728, he returned from a country walk too late to enter the city gates, and rather than return to Geneva the next morning, he chose to try his fortune. This adventure led him eventually to Turin, to the Hospice of the Holy Ghost, where, abjuring "the religion of my fathers," he became a Roman Catholic, apparently without serious awareness of what such a conversion meant for him. "I became a Catholic," he was to say at the end of his life, "but I always remained a Christian" (*ibid.*, vol. 1, p. 1013).

Self-education. Unable to find a means of livelihood in Turin, Rousseau went in 1729 to Annecy in Savoy, to live with Mme. de Warens, "the good woman" who had received him hospitably when he first fled from Geneva. The time he spent in Savoy, from 1729 to 1742, was a decisive period for his formation as a writer.

About thirty years old, Mme. de Warens was herself a new convert to Catholicism and something of an adventuress. She encouraged Rousseau's affection for her, and he lived with her until he finally resolved to seek his fortune in Paris. At first she treated him as a son, but after a time he became her lover. Rousseau's life in Savoy was both happy and free; according to the *Confessions*, those 12 years were "the one short period of happiness of my entire life."

The years he spent with Mme. de Warens, not only at Annecy but also at Chambéry and Les Charmettes, were chiefly years of study. Whereas the other great writers of the eighteenth century, Montesquieu, Voltaire, and even Diderot, were formally educated, Rousseau taught himself. Everything he learned, as he said in the *Confessions* with all the pride of an autodidact, he learned by himself. At Les Charmettes, his passion for reading was reawakened, and he ranged over all domains of learning, carefully jotting down excerpts from his readings in notebooks that became veritable "storehouses of ideas." When he began studying the sciences, he did geometry exercises, performed chemistry experiments, and even made astronomical observations. Finally he learned music. Although "born for this art," he had received no musical instruction, and at the time of his arrival at Annecy, he could hardly read a musical score. Ten years later, he was to be able both to compose music and to direct an orchestra; by a "determined study of the obscure books of Rameau" and other scholarly works, he had acquired a profound knowledge of musical composition and theory.

It was with this baggage of knowledge that he left Savoy in 1742. Like his departure from Geneva in 1728, this was also a flight. Rousseau felt that he no longer occupied the same place in Mme. de Warens' life. But this time he left with a specific goal—that of submitting to the Academy of Sciences the system of musical notation he had invented.

Early success. Rousseau arrived in Paris during the summer of 1742, equipped with only a few letters of recommendation and his system of musical notation. He had come to the city in quest of fame, but for ten years he was obliged, as Jean Guéhenno put it, to "mark time in the crowd of men of letters" (1948-1952).

He succeeded in interesting various ladies of Parisian society in his fate, and one of them obtained employment for him as secretary to the new French ambassador in Venice. The stay in Venice was important because it was there that he first conceived the ideas that were fully developed in his *Contrat social* (1762a). His conflicts with the ambassador, however, were such that after a year he was dismissed. Naively, he expected that the ambassador would be blamed and the secretary vindicated, but he was quickly disillusioned. From then on, he was convinced that there was no reason to expect any kind of justice from a social order founded on inequality of status.

Upon his return to Paris, he began a liaison with an uneducated young domestic servant, Thérèse Levasseur, who became his lifetime companion and who served him both as housekeeper and as nurse. According to the *Confessions*, several children were born from this liaison; all of them were placed in the Foundlings' Home. Although Rousseau later felt that it had been a "mistake" to abandon his children, he nevertheless did so, according to the *Confessions*, "without the slightest scruple." He could not afford to rear a family on his earnings as a writer; besides, he was only following "local custom," since in 1745 almost a third of all the infants born in Paris were abandoned to institutional care.

Two successes, one literary, the other musical, lifted Rousseau out of obscurity. In 1749, the Academy of Dijon, which was then one of the flourishing provincial academies, announced an essay contest dealing with the following question: "Has the progress of the sciences and arts contributed to the purification of morals?" Rousseau entered the contest and won the prize by replying "No." In his *Discours sur les sciences et les arts* (1750) he first developed a theme to which he reverted

constantly in his later work: the contrast between ancient and modern peoples. He found the former to be virtuous, by reason of their ignorance, their simplicity, and even their coarseness of manner, whereas the latter are too subtly refined not to be corrupt. Yet had historians paid closer attention to the *Discours*, they would have avoided the mistake of reducing Rousseau's thought to a simple antithesis between man's natural goodness and his corruption by society. This antithesis is doubtless of great importance, but it should not obscure his more basic premise that all peoples are precisely what their social institutions make them. Rousseau's essay provoked various polemics, including a refutation by the Polish king Stanislas, and these polemics undoubtedly gave Rousseau very useful publicity.

A short time later, Rousseau the musician was to have the same success as Rousseau the writer. In 1752 *Le devin du village* was played twice at Fontainebleau for Louis xv, and the following year several times at the Opéra. "Le devin du village," Rousseau said in the *Confessions*, "added the finishing touch to my popularity, and I became the most sought after man in Paris" (*Oeuvres complètes*, vol. 1, p. 369 in the Gallimard edition). Indeed, at this period he was known primarily as a musician, but he had the wisdom to give up music in order to devote himself entirely to literature.

Early writings about society. It was in the ten years of intense literary production from 1752 to 1762 that Rousseau composed his most important writings. The first of these was the *Discours sur l'origine de l'inégalité* (1755). It was a work of circumstance, since Rousseau was again answering a question proposed by the Academy of Dijon. However, the subject was so close to his own concerns that he could not have chosen a more appropriate one himself. For Rousseau, inequality is the original evil, the one that engenders all others. Thus, by opposing "the equality which nature established among men," to "the inequality which men have instituted," Rousseau, in this second *Discours*, made a case against life in society similar to the case against civilization that he had made in the first.

His article "Économie politique," published in 1755 in the fifth volume of the *Encyclopédie*, was written in the same period as the second *Discours*. The article is a short political treatise in which the author expounded his ideas on government, public education, and state finances. While the second *Discours* is essentially a work of criticism, intended to underline all the evils created for man

by life in society, by private property, and by social inequality, "Économie politique" shows the positive, constructive side of Rousseau's thought.

Montmorency. Rousseau had completed the writing of the *Discours sur l'origine de l'inégalité* in 1754 and had it printed in Holland in 1755. He dedicated it to the Republic of Geneva, and in the dedication he praised his native city, its government, and its magistrates, giving himself up completely to his republican enthusiasm and patriotic zeal. Upon his return to his native land in June 1754, he decided to become a Protestant again in order to resume his rights as a Genevan citizen. He attached so little importance to matters of cult and to those questions which divided the Christian confessions that he failed for the second time to attribute religious significance to the change. "Believing that there were not two ways for a reasonable man to be a Christian, I believed also," he wrote in the *Confessions*, "that all matters of formality and discipline in any state fall within the purview of the laws" (*Oeuvres complètes*, vol. 1, p. 392 in the Gallimard edition). Thus, his return to the religion of his fathers was, in effect, a civic act rather than a religious one.

In the patriotic joy of his homecoming, Rousseau may have intended to settle in Geneva. If such was indeed his intention, it was an idea which he quickly abandoned. Voltaire had just moved into Les Délices, quite near Geneva, and Rousseau knew well enough that there was not room for both of them in his native city. He also knew that he would be less free in Geneva than in France to publish his writings under his own name. This consideration weighed heavily in his decision to accept the invitation of Mme. d'Épinay to move to L'Ermitage, a summer house which she had prepared for him on her estate on the edge of the Montmorency forest. After so many years spent in Paris, "city of noise, smoke, and mud," Rousseau was delighted to return to country life. However, he stayed there less than two years; he moved in during April 1756 and left in December 1757, after a memorable quarrel with Mme. d'Épinay, with Grimm, and even with Diderot. The origins of the quarrel lay in Rousseau's infatuation with Sophie d'Houdetot, a sister-in-law of Mme. d'Épinay. The young countess encouraged his passion, if she did not share it; it was the great passion of Rousseau's mature life. The novel he was writing, *La nouvelle Héloïse* (1760), was one source of his involvement: he fell in love with Mme. d'Houdetot, seeing in her his own heroine Julie—a case of literary creation giving rise to events in real life.

The amorous involvement at L'Ermitage lasted barely four months. Mme. d'Houdetot ended all communication with Rousseau as soon as she saw herself compromised by his indiscretions. Rousseau suspected Diderot of having divulged the secret and, feeling himself betrayed, decided not merely to break with Diderot but to break with him publicly, which he did in the Preface to his *Lettre à M. d'Alembert* (1758).

Despite the break with Diderot and Mme. d'Épinay, Rousseau refused either to return to Paris or to leave the Montmorency forest, which he had made his "study." He stayed on at Montmorency for more than four years, first in a house he rented in the Mont-Louis park, and then in the Petit Château of the marshal of Luxembourg.

While at L'Ermitage, Rousseau abandoned once and for all the idea of writing a work entitled "La morale sensitive ou le matérialisme du sage." He postponed the final version of his *Dictionnaire de musique* (which was not finished until 1764 in Môtiers and not published until 1768 in Paris). He tried to finish a work on the abbé de Saint-Pierre as quickly as possible, and therefore he unfortunately gave up his original plan to analyze all the abbé's *projets* and to write his biography, for which, he felt, he "had collected some rather good materials." Instead, he dealt only with the *Projet de paix perpétuelle* and the *Polysynodie* (a proposal for multiple advisory councils), presenting a "critique" after each.

Shortly after moving to Mont-Louis, in February 1758, Rousseau wrote the *Lettre à M. d'Alembert sur les spectacles*. This was again a work prompted by circumstance. D'Alembert had written the article "Genève," published in the fall of 1757 in the seventh volume of the *Encyclopédie*. Two passages in the article, both inspired by Voltaire, caught Rousseau's attention—a malicious praise of the Genevan clergy ("a number of Genevan pastors have no other religion than pure socinianism") and a plea for the establishment of a theater in the city. Preferring to let the pastors defend themselves, Rousseau passed rapidly over the religious question, and he devoted the greater part of the work to public entertainment generally, not simply to the theater, as is often supposed. Indeed, the *Lettre à M. d'Alembert* contains, in addition to Rousseau's criticism of the theater and of actors, a rough outline of a sociology of entertainment, considering entertainment in relation to the society for which it is intended. Thus, monarchies can support the luxury of a theater, but republics, and particularly small cities, require forms of enter-

tainment more appropriate to them, such as festivals, public balls, games, dances, concerts, gymnastic competitions, and military parades; in short, free entertainment held in the open air.

According to the *Confessions*, Rousseau wrote the *Lettre à M. d'Alembert* in only three weeks and then devoted his time to the completion of his novel, which was printed in Holland by Marc-Michel Rey. *La nouvelle Héloïse* appeared in the beginning of 1761, under the title *Lettres de deux amans, habitans d'une petite ville au pied des Alpes, recueillies et publiées par J.-J. Rousseau*. It enjoyed an immediate and huge success with the public and ever since has been counted among the masterpieces of European literature.

**Thoughts on childhood.** With *La nouvelle Héloïse* finished, Rousseau returned to two other major projects: *Émile* (1762b), which was to present his system of education, and the "Institutions politiques." He did finish a full-scale version of the first; the second was reduced to a short treatise, to which he gave the title *Du contrat social, ou principes du droit politique* (1762a). Both works have become classics, in pedagogy and political science, respectively.

An innovator in almost all domains, Rousseau gave proof of his originality especially in his treatise on education, which has so much in common with the pedagogy of our own time. His object in *Émile* was not to make a craftsman or a gentleman of his pupil; his aim was to "educate him to be a man," for, as he said, "a natural education should fit him for any human vocation." Instead of letting himself become imprisoned within the narrow framework of pedagogy, Rousseau conceived of his book as a reflection upon man and man's estate. "It matters little to me," he said further, "that I have written a novel. Human nature itself makes a rather fine novel" (*Oeuvres complètes*, vol. 2, p. 387 in the Hachette edition). But while the object of education is to form a man, its subject is the child. Rousseau reproached his predecessors for having forgotten this fact, and he blamed adults in general for being unable to imagine any mentality other than their own. "Childhood," he said, "has its own ways of seeing, thinking, and feeling; nothing is more foolish than to try to replace them with ours" (*ibid.*, vol. 2, p. 37). There is, then, a mentality peculiar to the child, and the first aim must be to understand it. Rousseau is probably the first to have linked the science of education to the scientific understanding of the child, and for this reason he is rightfully recognized today as the precursor and even the founder of child psychology.

Nevertheless, his conception of childhood re-

mained theoretical rather than experimental, for it rested almost entirely on an analogy drawn between the state of childhood and the state of nature. The child is as alone in human society as the savage in the thick of his woods. It is because of the child's natural solitude that Rousseau warned against premature socialization. "Parents who live in civilized society bring their children into it too young" (*ibid.*, vol. 2, p. 51). The second mistake to avoid is that of reasoning with children, since the other characteristic common to both childhood and the state of nature is a life governed by pure instinct; reason awakens and develops only with age and through social relationships. This is why Rousseau divided education into two distinct phases: the first, education concerned with the world of things, occupies the period of childhood; the second, moral education, must be put off until the beginning of adolescence, when the young man, having become involved in social relationships, develops his reason naturally, rather than prematurely, because he needs it to control his awakening passions. "The proper study of man is the study of his relationships. As long as he knows himself only through his physical being, he must study himself in relation to things; this is the program of his childhood: when he begins to sense his moral being, he must study himself in relation to men; this is the program of his entire life . . ." (*ibid.*, vol. 2, p. 184).

**The "Social Contract."** While *Émile* is a treatise on man, the *Contrat social* is a treatise on the citizen, but both are inspired by the same ideal—they are intended to safeguard liberty, which is constantly threatened by social relationships and social institutions. "The greatest good," said Rousseau in *Émile*, "is not authority, but liberty." Relationships of authority are almost always arbitrary or tend to become so. "Dependence among men being without order or rule," authority gradually transforms itself into domination and obedience into servitude. If, therefore, liberty is to be preserved, this dependence among men must be eliminated or at least subjected to regulation. From this point of view, the requirements of liberty create the same task for the legislator as for the educator. Natural education, we have seen, consists in withdrawing the child from dependence upon adults in order to subject him to dependence upon things. Similarly, the art of politics consists in making each citizen extremely dependent upon the polis in order to free him from dependence upon other citizens (*Contrat social*, book 2, chapter 12 in *Oeuvres complètes*, vol. 3, p. 394 in the Gallimard edition).

Not only are the various clauses of the *Contrat*

social finally reducible to a single stipulation—"the total surrender of each individual with all his rights to the whole community" (*ibid.*, vol. 3, p. 360)—but the contract or pact correspondingly establishes the absolute supremacy of the state over all its members. Unlike Locke or Montesquieu, Rousseau asserted no fundamental law, nor did he place constitutional limitations on sovereignty. "It is the essence of Sovereign Power," Rousseau said in 1764, in his *Lettres écrites de la montagne*, "to be illimitable; it is omnipotent or it is nothing" (*ibid.*, vol. 3, p. 826). Rousseau's political doctrine excludes any balance or equilibrium of powers; there is in the state only one supreme power, to which all others are subordinated. The sovereign people can at any time change its rulers and its laws or modify the form of its governmental administration and the constitution of the state. In principle there is nothing it cannot do.

It is understandable, therefore, that a considerable number of historians have reproached Rousseau for having paid only lip service to the cause of liberty and for having in fact opened the gates to despotism, collectivism, and totalitarianism. In France, he has been blamed for having sacrificed, through his theory of sovereignty, the rights of the individual to the omnipotence of the state. This error, said Benjamin Constant in 1815, made his *Contrat social*, "which is often invoked in behalf of liberty, the most terrible weapon of all types of despotism" ([1815] 1957, p. 1105). A century later, the jurist Léon Duguit called Rousseau the "source of all the doctrines of dictatorship and tyranny, from the doctrines of the Jacobins in 1793 to the Bolshevik doctrines of 1920" (1922, p. 135). In England, and elsewhere, the *Contrat social* did not arouse such impassioned discussion as in France. Nevertheless, it is significant that the scholarly editor of *The Political Writings of Jean-Jacques Rousseau*, C. E. Vaughan, considered it anti-Lockean: "... while the Contract of Locke," he says, "is expressly devised to preserve and confirm the rights of the individual, that of Rousseau ends, and is intended to end, in their destruction. . . . One is a charter of individualism. The other, with certain crucial qualifications to be noted shortly, is an extreme form of collectivism" ([1915] 1962, p. 48). More recently, J. L. Talmon stated that Rousseau's ideas were to blame for the "rise of totalitarian democracy" (1952).

These interpretations, based on the concepts of the "total surrender" of individual rights ("l'aliénation totale") and of the absolute sovereignty of the state over all its members, draw conclusions from the *Contrat social* that are fundamentally opposed

to the intentions of its author. Indeed, for Rousseau, liberty was the most precious of possessions, a gift which nature has made to men. They can no more be deprived of it rightfully than they can be deprived of life itself; nor can they be permitted to divest themselves of it for any price whatsoever. The social pact should not be interpreted as abrogating, in effect, a right which Rousseau declared inalienable and inseparable from the essential character of man. Rousseau affirmed that the surrender of rights is only apparent and that in the end individuals regain the rights which they appear to have given up. "Instead of a surrender," he said, "they have only made a profitable exchange" (*Contrat social*, book 2, chapter 4 in *Oeuvres complètes*, vol. 3, p. 375 in the Gallimard edition). In effect, the social contract is designed to secure or to restore to individuals in the state of civilization the equivalent of the rights they enjoyed in the state of nature.

The best interpreters of Rousseau, including Vaughan, have asserted that the theory of the general will constitutes a guarantee of individual rights, rather than their sacrifice. By the social pact individuals place themselves under "the supreme direction of the general will," and, in Rousseau's definition, it is "the exercise of the general will" that is sovereignty. Rousseau replaced the sovereignty of kings with the sovereignty of the people. But even this is not the essential safeguard to liberty. While the sovereign people cannot harm all its members—for this would be to harm itself—nonetheless this scarcely constitutes assurance that it cannot harm a single individual or that it cannot sacrifice the minority to the interests of the majority. This is why Montesquieu, for example, spoke of the "despotism of all." But such an eventuality is rendered impossible in Rousseau's system by the fact that the general will can never rule on individual cases or issues, but imposes the same sacrifices and confers the same advantages upon all citizens. If one individual is wronged, all are thereby wronged. The equality established among all citizens by the general will is their protection against any abuse of power by the sovereign. Since, in Rousseau's system, the sovereign authority cannot exceed "the limits of the general covenants," it follows that sovereignty, although absolute in principle, is always limited in practice.

Rousseau presented still another argument: that the citizen, by subjecting himself to the general will and to the laws which it prescribes, obeys no one but himself and, therefore, "remains as free as he was before." This reasoning is not entirely without difficulties, however, for in point of fact

the "general will" is not the "will of all." The general will is a corporate will, the will of the corporate people. But this body is made up of citizens, and their general will *as citizens* may well be different from the particular wills they have *as individuals*. The general will cannot finally prevail in the individual heart unless the man disappears behind the citizen and changes his "nature," so to speak, in order to identify himself with the polis. To make a man a citizen, it is thus indispensable to transform the human mentality. In the *Contrat social*, Rousseau entrusted this task to the legislator, but according to *Émile*, it is the proper goal of public education, without which there can be no citizens.

Although Rousseau affirmed in Book 4 of the *Contrat social* that "since man is born free and his own master, no one can govern him without his consent" (*Oeuvres complètes*, vol. 3, p. 440 in the Gallimard edition), it is doubtful whether the "consent" of the governed in his system has the same importance as in Locke's *Two Treatises of Government*: the ideal of "government by consent" remains closer to liberal theories of the state than to the equalitarian conception of Rousseau.

By the logic of Rousseau's doctrine, it is precisely because the general will maintains equality among citizens that its exercise is not susceptible to abuse. Abuses of power and risks of oppression can come only from the intermediate body which is responsible for the enforcement of the laws or the administration of the state. (According to the terminology created by Rousseau, which subsequently became common, this intermediate body is called the government, as distinguished from the sovereign.) Sovereignty being nothing else than the exercise of the general will, the sovereign can act only by means of laws and consequently must entrust the executive power to a subordinate body. But this body, like all collective bodies, tends to place its own corporate interest before the common interest and to substitute itself for the sovereign. The true political problem for Rousseau consisted, thus, in keeping the government within the limits of its power and in preventing it from becoming master of the state by usurping that sovereignty, or legislative power, which can belong only to the people.

The great distance that separates Rousseau's political doctrine from Montesquieu's emerges clearly. Not only is Rousseau's doctrine equalitarian and antihierarchical; it is at the same time republican and antimonarchist. To be sure, he retained monarchy among the forms of government, but he saw kings simply as magistrates or officers respon-

sible for the enforcement of the laws. This qualification in effect withdraws from kings the rights of sovereignty and confers these rights solely upon the people. As Rousseau's contemporaries observed, and as the Jesuit G. F. Berthier in particular noted in his *Observations sur le Contrat social* (1789), it was tantamount to granting recognition neither to monarchy nor to aristocracy, but only to democracy.

Last years. Rousseau was clearly running great risks by publishing such a book as the *Contrat social* under his own name. It was published in Amsterdam by Marc-Michel Rey and distributed in the spring of 1762. Its circulation was forbidden in France, but no further measures were taken against it. *Émile*, however, unleashed a storm. It had been printed in Paris by Duchesne (under the fictitious editorship of Jean Néaulme of Amsterdam) and was offered for sale in May 1762. Rousseau had inserted in the work a section which had originally been separate and in which he presented his religious ideas, *Profession de foi du vicaire savoyard*. This was the pretext seized upon by the Parlement of Paris to condemn the work and to issue a writ for Rousseau's arrest on June 9, 1762. (The Parlement proceeded against him with such severity because it was about to expel the Society of Jesus from France and wished to strike at unbelievers at the same time.) However, the writ of arrest was not enforced with much haste, and Rousseau was able to leave France without being harassed.

Where was he to go? Even had he wished, he could not have gone to Geneva, for on June 19, ten days after the writ of the Parlement, the Genevan Advisory Council condemned both *Émile* and the *Contrat social*, charging that both works were "destructive of the Christian religion and of all governments." During his years of exile Rousseau constantly sought a suitable place to stay, an agonizing problem for a man 50 years old and afflicted with a painful infirmity. Switzerland was the country he preferred, but where in Switzerland? First Rousseau resided for three years—July 1762–September 1765—at Môtiers in the principality of Neuchâtel, which then belonged to the king of Prussia. There he prepared two polemical writings in defense of his work, an open letter addressed to the archbishop of Paris, Christophe de Beaumont, which he composed during the winter of 1762 and published the following year, and the *Lettres écrites de la montagne* (1764), an answer to the *Lettres écrites de la campagne*, written by the prosecuting attorney, J.-R. Tronchin. He declined responsibility, however, for the agitation on his behalf by his Genevan

friends and preferred to renounce his Genevan citizenship in 1763, rather than involve himself in a political quarrel. His vocation was to write, not to become a party leader.

Rousseau was driven from Môtiers by a popular demonstration, the importance of which he exaggerated, and subsequently he was expelled from the Île Saint-Pierre by the Bernese authorities. He returned to Paris without being harassed, but only for a temporary stay. Then, at the invitation of David Hume, he agreed to go to Scotland, but quarreled with his host. Rousseau stayed almost a year and a half in England, first on the outskirts of London, then at Wootton in Derbyshire, and finally returned to France in May 1767. Here, for three years, he lived the life of a hunted man, first at Trye-le-Château in the Oise region, then at Bourgoin and at Monquin in the province of Dauphiné. During this time he changed not only his residence but also his name, signing his letters as "Renou."

In 1770 Rousseau received assurance that he could reside in Paris without being disturbed and thereupon moved into small quarters on the rue Plâtrière. For several years he was obsessed to the point of madness by the idea that there was a plot or a kind of universal conspiracy against his person and his writings. He never did wholly shake off this obsession, although toward the end of his life he succeeded in regaining a certain peace of mind. In Paris he spent his time copying music (which was his livelihood), gathering herbs, and writing.

He did not stop writing after the publication of his three great works. During his stay in Môtiers in 1765, he drafted the *Projet de constitution pour la Corse*, which was never finished, and in Paris in 1772, *Considérations sur le gouvernement de Pologne*. In the first of these two works, the author of the *Contrat social* applied his "principles" to the problems of legislating for a newly independent people and in the second he proposed reforms to a proud nation threatened by powerful neighbors.

His primary concern was a vast project which he had been contemplating for a long time, his autobiography. It was an undertaking which would require several years of unceasing work. Rousseau knew this and, despairing of bringing the project to completion, wrote in 1762 the four autobiographical *Lettres à M. de Malesherbes*. Later, however, he succeeded in drafting his *Confessions*, which were composed in two different periods, from 1765 to 1767 and in the winter of 1769/1770. The *Confessions* were written largely for the pleasure of knowing himself and reliving his past, but the

three dialogues, written in the period 1772-1775 and entitled *Rousseau, juge de Jean-Jacques*, were composed while he was haunted by fears of persecution. He wrote this strange book to vindicate himself: "I should willingly consent," he said, "to not existing at all in the memory of men, but I cannot consent to remain there forever dishonored by calumny" (*Oeuvres complètes*, vol. 1, p. 953 in the Gallimard edition). His obsession with a conspiracy, which dominated the dialogues, persisted to some extent in his *Rêveries du promeneur solitaire* (1782), but Rousseau had largely regained his serenity when he wrote these reflections. None of his autobiographical writings was published until after his death, which came suddenly on July 2, 1778, in Ermenonville. He was buried at Ermenonville, and pilgrimages were made to his tomb there until the Convention ordered his remains transferred to the Panthéon.

In our day, sociologists and ethnologists have recognized Rousseau, the self-styled "apologist of nature," as a forerunner of the social sciences and perhaps, even, as their founder. Émile Durkheim said succinctly of the *Discours sur l'origine de l'inégalité*: "Rousseau demonstrated a long time ago that if all that comes to man from society were peeled off, there would remain nothing but a creature reduced to sense experience and more or less undifferentiated from the animal" (1906, p. 132). To rise above the animal stage, men must become sociable and therefore must relinquish the state of nature. Such appears to be the teaching of the second *Discours*. According to Rousseau, what distinguishes man from the animal is his perfectibility. But perfectibility is closely connected with sociability, which permits it to develop, whereas in the state of nature it is only a "potential faculty." Rousseau held that "Man in a state of isolation always remains the same; only in society does he progress" (*Oeuvres complètes*, vol. 3, p. 533 in the Gallimard edition). So long as he lives in the isolation of the state of nature, he exists only as a physical being. As a moral being he is formed in society, for his passions, his reason, and even his conscience become active and develop only in social relationships. It is true that perfectibility brings in its wake a multitude of evils from which man in the state of nature was exempt, but "nature does not retrogress." From this it follows that human history begins with life in society.

Such considerations as these anticipated later developments in social science. Claude Lévi-Strauss has recently shown that ethnology is indebted to

Rousseau and that it has borrowed from him the methodological rule he stated in the *Essai sur l'origine des langues*: "To study men, we must look close by; to study man, we must learn to look afar; if we are to discover essential characteristics, we must first observe differences" (*Oeuvres complètes*, vol. 1, p. 384 in the Hachette edition). This passage shows clearly what kind of research Rousseau thought necessary for the understanding of man; sociology had its objective fixed in advance, so to speak, by the precept of *Émile*: "We must study society by studying men, and men by studying society. Those who expect to treat political and moral philosophy as separate entities will never understand anything about either" (*ibid.*, vol. 2, p. 206).

#### WORKS BY ROUSSEAU

- (1750) 1946 *Discours sur les sciences et les arts*. Critical edition. The Modern Language Association of America, Monograph Series, No. 15. New York: The Association; London: Oxford Univ. Press. → First published as *Discours qui a remporté le prix à l'Académie de Dijon*.
- (1750-1755) 1964 *The First and Second Discourses*. Edited with an introduction and notes by Roger D. Masters. New York: St. Martin's. → Contains *Discourse on the Sciences and Arts* and *Discourse on the Origin and Foundation of Inequality*. First published in French.
- (1752) 1964 *Le devin du village*. Volume 2, pages 1093-1114 in Jean-Jacques Rousseau, *Oeuvres complètes*. Paris: Gallimard.
- (1755) 1941 *Discours sur l'origine et les fondements de l'inégalité parmi les hommes*. Cambridge Univ. Press.
- (1758) 1948 *Lettre à M. d'Alembert sur les spectacles*. Critical edition, by M. Fuchs. Lille: Glard. → Translated into English as *Politics and the Arts: Letter to M. d'Alembert on the Theatre* and published by the Free Press in 1960.
- (1761) 1964 *La nouvelle Héloïse*. Volume 2, pages 5-796 in Jean-Jacques Rousseau, *Oeuvres complètes*. Paris: Gallimard.
- (1762a) 1961 *The Social Contract*. London: Dent. → First published in French.
- (1762b) 1963 *Émile*. London: Dent; New York: Dutton. → First published in French.
- (1762c) 1873 *Profession de foi du vicaire savoyard*. Volume 2, pages 236-327 in Jean-Jacques Rousseau, *Oeuvres complètes*. Paris: Hachette.
- (1762d) 1928 *Lettres à M. de Malesherbes*. London: Scholartis Press.
- 1763 *Jean-Jacques Rousseau, citoyen de Genève, à Christophe de Beaumont, archevêque de Paris*. Amsterdam: Rey.

- (1764) 1962 *Lettres écrites de la montagne*. Neuchâtel (Switzerland): Ides et Calendes.
- (1765-1770) 1960 *The Confessions of Jean Jacques Rousseau*. 2 vols. New York: Dutton; London: Dent. → Written between 1765 and 1770; first published between 1782 and 1789 in French.
- (1772) 1873 *Considérations sur le gouvernement de Pologne*. Volume 5, pages 237-302 in Jean-Jacques Rousseau, *Oeuvres complètes*. Paris: Hachette.
- (1772-1775) 1959 *Rousseau juge de Jean-Jacques*. Volume 1, pages 657-992 in Jean-Jacques Rousseau, *Oeuvres complètes*. Paris: Gallimard.
- (1781) 1877 *Essai sur l'origine des langues*. Volume 1, pages 370-408 in Jean-Jacques Rousseau, *Oeuvres complètes*. Paris: Hachette.
- (1782) 1948 *Les rêveries du promeneur solitaire*. Critical edition by John S. Spink. Paris: Didier. → An English translation, *The Reveries of a Solitary*, was published by Routledge in 1927.

*Correspondance complète*. Édition critique, établie et annotée par R. A. Leigh. Vols. 1-4. Geneva: Institut et Musée Voltaire, Les Délices, 1965- → Volume 1 contains letters 1-97, dating from 1730 to 1744.

*Correspondance générale de J.-J. Rousseau*. 20 vols. Annotated by Théophile Dufour. Paris: Colin, 1924-1934. → Letters dated 1728-1778.

*Oeuvres complètes*. 12 vols. Paris: Hachette, 1871-1877. → Customarily designated the "vulgate" edition of Rousseau's works. See especially Volumes 1 and 2: *Discours* and *Émile*. Translations have been provided by the editors.

*Oeuvres complètes*. 3 vols. Edited by Bernard Gagnebin and Marcel Raymond. Bibliothèque de la Pléiade. Paris: Gallimard, 1959-1964. → Volumes published as of 1964 are the following: Volume 1: *Les confessions*; *Autres textes autobiographiques*. Volume 2: *La nouvelle Héloïse*; *Théâtre*; *Poésies*; *Essais littéraires*. Volume 3: *Du contrat social*; *Écrits politiques*. Translations have been provided by the editors.

*Political Writings*. 2 vols. Edited from the original manuscripts and authentic editions, with an introduction and notes by C. E. Vaughan. New York: Wiley, 1962. → This edition was first published in 1915.

## RULE OF LAW

See CONSTITUTIONAL LAW; JUDICIAL PROCESS; JUDICIARY.

## RULES OF THE GAME

The concept "rules of the game" is frequently used in contemporary political science, albeit with a variety of meanings. Most commonly, the concept denotes widely shared beliefs about *how* the government, or various categories of political actors, *ought* to behave. "Rules of the game" are, therefore, essentially normative and procedural. The concept is rarely used to refer to formal or written rules—statutes, constitutions, court decisions, and the like—but usually refers to informal or unwritten rules, attitudes, and expectations. There is far less agreement, however, on the precise content of these rules, on how widely shared they are, or on what functions they perform.

The historical origins of the concept are as obscure as its psychological appeal is clear. Politics—particularly as practiced in regimes recognizing the legitimacy of overt, organized opposition and successfully limiting the use of force and fraud as political techniques—has many similarities to a game. Competing players pursue conflicting goals by means of varying strategies within the context of an agreed-upon set of rules. The outcome of the game—be it politics, football, or poker—depends partly upon the relative skill of the players and partly on chance factors over which the players have little or no control. These similarities between politics and games occurred to politicians and political journalists generations ago (Kent 1923), well before political scientists made use of the metaphor or von Neumann and Morgenstern (1944) published their mathematical theory of games [see GAME THEORY]. Recently, political scientists have sought to determine the content and consequences of the rules of the game of politics through empirical observation, rather than deriving them deductively from an abstract model of a generalized game, as in mathematical game theory. The latter approach results in rules about strategies that rational players will follow in various hypothetical conflict situations; the "rules of the game" that political scientists have written about are widespread normative beliefs which exist in the real world of politics.

### Rules of the game and political democracy

Political philosophers of varying persuasions—Edmund Burke, Walter Bagehot, Alexis de Tocque-

ville, Harold Laski, to name a few—have argued that political democracy “. . . presupposes a people so fundamentally at one that they can safely afford to bicker” (Lord Balfour quoted in Friedrich [1942] 1950, p. 153). It is characteristic of this body of literature that no attempt is made to specify what these “fundamentals” are. If this line of argument implies that there can be no basic cleavages within a democratic polity, or that a democratic citizenry must be in agreement on the goals of governmental action, this position is logically absurd and historically false (*ibid.*, chapter 5). But it is possible to interpret at least some of these writers as meaning only that the mass of the citizenry in a political system must be agreed on the rules of the game before political democracy is possible. This more restricted view lies at the heart of a recent, empirically oriented political theory. [See DEMOCRACY.]

David B. Truman (1951) assigns an important role to mass acceptance of “the rules of the game” in the functioning of American democracy. To Truman and his followers, the interest group—a set of persons interacting on the basis of one or more shared attitudes—is the basic unit of political analysis. Politics is visualized as the patterned interactions of these groups. A number of factors, over and above simple competition between interest groups, result in the stability of such a system. First, the average person belongs to a number of interest groups. In order to grow in size and to maintain internal cohesion, an interest group must, therefore, consider the other interests and group affiliations of its members. Second, interest groups vary in the extent of their formal organization and their degree of involvement in politics. Every shared attitude (interest) can serve as the base of a group; every group not currently making claims on others through attempts to influence the governmental apparatus can, if threatened, become a political interest group. Existing political interest groups must therefore pay heed to potential interest groups or face the consequences of creating their own opposition. Third—and most important for our purposes—widespread agreement on the rules of the game exists among the citizenry and officialdom. While these interests (attitudes) are not generally organized into political interest groups, they do represent powerful potential groups. Active groups, by anticipating the possible development of these attitudes into groups active in the political arena, tend to play the game of politics within the confines of these broad rules of conduct. “It is thus multiple memberships in potential groups based on widely held and accepted interests that serve as a balance wheel in a going political system like that of the

United States. . . . Without the notion of multiple memberships in potential groups it is literally impossible to account for the existence of a viable polity such as that in the United States or to develop a coherent conception of the political process” (Truman [1951] 1965, p. 514). These “widely held and accepted interests” are explicitly identified by Truman as the rules of the game. Potential groups are their guardians. [See POLITICAL GROUP ANALYSIS.]

Recent research on the attitudes of the electorate in the United States casts doubt upon this line of analysis by demonstrating that, at least in the United States, mass agreement with “the rules of the game” is much less widespread than had previously been assumed to be the case. Prothro and Grigg (1960) confronted random samples of registered voters in two widely separated cities in the United States with a set of general statements about political democracy and a second series of statements which apply these general rules to specific cases. They found overwhelming consensus in favor of the general statements, but “when these broad principles are translated into more specific propositions . . . consensus breaks down completely” (p. 286). On 40 per cent of the specific statements in one city, and 60 per cent in another, a clear majority of the voters expressed antidemocratic preferences. Prothro and Grigg did find, however, overwhelming agreement with *both* the general and specific statements about democracy among the highly educated—a finding which led them to speculate that widespread agreement on the rules of the game at the elite level may be a precondition for democratic politics, but that on the mass level it apparently is not. The relative apathy of the mass electorate, and widespread habits of democratic behavior, may account for the survival of political democracy without mass consensus on the rules of the game. [See CONSENSUS.]

Robert Dahl, in his study of New Haven, Connecticut (1961), found much the same phenomenon. The same minority of the population that possesses the highest levels of political interest, skills, and resources also possesses the greatest commitment to the rules of the game of democratic politics. The vast majority of the citizenry may not agree with these rules, but lack the interest, skills, and resources to do much about it.

Herbert McClosky (1964) provides data on attitudes toward the rules of the game of a national sample of adult American citizens (Table 1). It is clear that a sizable minority of American citizens do not accept the rules of the game, at least as measured by these statements. The same question-

Table 1 — Agreement with the rules of the game in the United States

Statement	Political influentials (N = 3,020)	General electorate (N = 1,484)
	Per cent disagreeing, i.e., giving response consistent with rules of the game*	
(1) There are times when it almost seems better for the people to take the law into their own hands rather than wait for the machinery of government to act.	87	73
(2) The majority has the right to abolish minorities if it wants to.	93	71
(3) We might as well make up our minds that in order to make the world better, a lot of innocent people will have to suffer.	73	58
(4) If congressional committees stuck strictly to the rules and gave every witness his rights, they would never succeed in exposing the many dangerous subversives they have turned up.	75	53
(5) I don't mind a politician's methods if he manages to get the right things done.	74	58
(6) Almost any unfairness or brutality may have to be justified when some great purpose is being carried out.	87	67
(7) Politicians have to cut a few corners if they are going to get anywhere.	71	57
(8) People ought to be allowed to vote even if they can't do so intelligently.	66	48
(9) Bringing about great changes for the benefit of mankind often requires cruelty and even ruthlessness.	81	69
(10) Very few politicians have clean records, so why get excited about the mudslinging that sometimes goes on?	85	62
(11) It is all right to get around the law if you don't actually break it.	79	70
(12) The true American way of life is disappearing so fast that we may have to use force to save it.	87	65

\* In the original study, agreement with statements 1-7 and 9-12 and disagreement with statement 8 were taken to indicate rejection of the rules of the game. In order to avoid confusion, the percentages in the table show the proportion of the two samples indicating agreement with the rules of the game. "Don't know" responses, which averaged less than 1 per cent, were ignored.

Source: Adapted from McClosky 1964, p. 365, table 1.

naire was administered to the delegates and alternates to the Democratic and Republican national party conventions in 1956. Their responses (summarized under the "Political influentials" column in Table 1) indicate far wider agreement with the rules of the game among these political activists than among rank-and-file Americans.

Assuming that the United States is a reasonable approximation of a political democracy, these studies suggest that agreement about the rules of the game on the mass level is less important than either the philosophers or the group theorists argue. Elite agreement on these rules may well be a necessary condition for a successful political democracy, but only additional research conducted in a variety of political systems will tell us whether the hypothesized relationship between rules of the game and political democracy needs merely to be revised or whether it must be abandoned altogether.

### Rules of the game in legislatures

A second area of political science in which the concept "rules of the game" is of central importance is the field of legislative behavior research. Contemporary students have not only found that unwritten rules of behavior exist in a variety of legislative settings, but they have also been able to describe the content of these normative expectations, estimate how widely they are accepted, describe how they are enforced, and suggest their consequences for the operation of legislative bodies.

While observers of legislative bodies have long commented upon the apparent importance of informal understandings and unwritten rules in their operation, the first systematic study of the rules of the game in a legislative body was Matthews' study (1960) of the behavior of United States senators.

The first unwritten rule of Senate behavior, according to Matthews, is that new members are expected to serve a proper apprenticeship. The freshman senator receives the committee assignments the others senators do not want; the same is true of his office suite and his seat in the chamber. In committee rooms he is assigned to the end of the table. He is expected to do more than his share of the thankless and boring tasks of the Senate, to keep his mouth shut, to listen and learn. According to the unwritten rules of the chamber, the freshman is to accept such treatment as a matter of course. Those who do not, encounter thinly veiled hostility and loss of esteem.

The great bulk of the Senate's work is highly detailed, dull, and politically unrewarding. According to the rules of the game in the Senate, it is to these tasks that a senator ought to devote a major share of his time, energy, and thought. Moreover, a senator ought to specialize, to focus his time and attention on the relatively few matters which come before his committees or that directly and immediately affect his state. Still another rule of Senate behavior is that political disagreement should not

influence personal feelings, that senators should avoid personal attacks on colleagues and strive for impersonality in debate. Moreover, senators must be willing to bargain—to operate on the basis of the reciprocal trading of favors. This requires self-restraint, tolerance, and an essentially nonideological approach to political life. Finally, senators are expected to display a high degree of institutional patriotism, to believe that the United States Senate is the greatest legislative body in the world, and to prefer serving there to holding any other public office in the land.

These norms perform important functions. They provide motivation for the performance of legislative duties that would not otherwise be performed. They encourage the development of expertise and division of labor and discourage those who would challenge it. They soften the inevitable personal conflict of a legislative body so that adversaries and competitors can cooperate. They encourage senators to become "compromisers" and "bargainers" and to use their substantial powers with caution and restraint (Matthews 1960, pp. 102–103). Without these rules of the game, the Senate could hardly operate in anything like its present form.

Yet while the consensus about these norms is impressive, they are not universally accepted or lived up to. Men who come to the Senate after distinguished careers in public or private life find serving an apprenticeship a trying experience. Members of the chamber with active presidential ambitions are unlikely to build a national reputation through faithful adherence to the rules of the game. Men with highly insecure seats, or those representing unusually diverse and complex constituencies, often find the injunctions about legislative specialization and self-restraint in floor debate difficult to reconcile with the exigencies of political survival. Finally, while senators are necessarily tolerant of differences of political viewpoint, the ease with which senators can conform to these informal expectations depends upon their ideological position. A man elected to the Senate as a "liberal" or "progressive" or "reformer" is under pressure to produce legislative results. The people who voted for him want national legislative policy changed. Yet if the liberal senator gives in to the pressure for conformity to the rules of the game, he must postpone the achievement of these objectives. If he presses for these objectives regardless of his junior position, he will become tabbed a nonconformist and will lose popularity with his colleagues. This might not be so serious a sanction if respect by one's colleagues were not extremely helpful in get-

ting legislation passed. "In the Senate," one member is quoted as saying, "if you don't conform, you don't get many favors for your state. You are never told that, but you soon learn" (Matthews 1960, p. 114).

Thus, one can describe some of the rules of the game in the Senate, and suggest how they are enforced and how they contribute to the operation of that body. But there is as yet very little evidence on the extent of agreement with these norms. Ralph Huitt (1961), for example, has argued that the degree of consensus on these norms is less than Matthews' study implies.

A study of the legislatures of California, New Jersey, Ohio, and Tennessee conducted by John Wahlke, Heinz Eulau, William Buchanan, and Roy Ferguson (see Wahlke et al. 1962) is based upon interviews with virtually every member of the bicameral legislatures of these four states and is therefore able to handle this particular question more satisfactorily. The rules of the game most frequently mentioned by these legislators are presented in Table 2. The first thing to notice about this listing is its substantial similarity to the rules Matthews found to be operative in the U.S. Senate. Moreover, the findings of Wahlke and his collaborators support the view that these rules are generally understood and accepted by virtually all members of these four state legislatures. "Of all respondents, only two perceived no rules of the game; over half readily named at least four rules . . ." (Wahlke et al. 1962, p. 143). Moreover, the rules mentioned comprised, on the whole, "a body of mutually compatible rules which does not normally confront legislators with the dilemma of choosing among contradictory rules . . . not a single respondent suggested the existence of conflicting sets of rules, each with its own set of proponents . . ." (*ibid.*, p. 148). Almost all the state legislators interviewed recognized that these rules were more or less systematically enforced by such informal but highly effective sanctions as obstruction of the nonconforming members' bills, social ostracism, mistrust, and loss of political perquisites and rewards. The authors conclude that these rules of the game are highly functional for the legislative chambers they have studied. They create group cohesion and morale, promote predictability of legislator behavior, restrain and channel conflict, and expedite the conduct of legislative business.

It is at present impossible to say to what extent these unwritten rules of the game are generally found in democratic legislative bodies or are merely a product of uniquely American factors. Wahlke and his collaborators found some intriguing differ-

Table 2 — Rules of the game most frequently perceived by legislators in four American states (in per cent)<sup>a</sup>

Rules <sup>b</sup>	California (N = 104)	New Jersey (N = 78)	Ohio (N = 160)	Tennessee (N = 119)
(1) Performance of obligations: Keep your word; abide by commitments	64	47	28	24
(2) Respect for other members' legislative rights: Support other members' local bills if they don't affect you or your district; don't railroad bills through; etc.	32	26	24	47
(3) Impersonality: Don't deal in personalities; don't engage in personal attacks on other members; etc.	30	27	32	31
(4) Self-restraint in debate: Don't talk too much; don't speak about subjects on which you're uninformed	17	9	18	59
(5) Courtesy: Observe common courtesies; be friendly and courteous even if you disagree	19	19	24	26
(6) Openness of aims: Be frank and honest in explaining bills; don't conceal real purpose of bills or amendments	24	8	22	12
(7) Modesty: Don't be a prima donna or publicity seeker	9	19	23	21
(8) Integrity: Be honest, a man of integrity	13	19	18	11
(9) Independence of judgment: Don't be subservient to groups or individuals outside of legislature	16	19	11	14
(10) Personal virtue: Exhibit high moral conduct, no drunkenness or immorality	13	0	24	8
(11) Decisiveness: Take a stand, don't vacillate	10	8	11	15
(12) Unselfish service: Don't be an opportunist; don't use your legislative position for your personal advantage	5	19	14	4

a. Percentages do not equal 100, because most respondents named more than one rule.

b. Fewer than half the rules mentioned are summarized above.

ences in the perceived rules of the game in the four states they studied. If the informal rules of the game serve to complement the formal aspects of legislative organization and procedures in promoting the viability of legislatures and the attainment of their goals, then they should be expected to vary—at least to some degree—as these factors change from one political system to the next.

Allan Kornberg's analysis of the rules of the game in the Canadian House of Commons (1964) is suggestive on this question. Using essentially the same techniques as Wahlke and his collaborators, he found a set of unwritten rules that were remarkably similar to those found earlier in the American Senate and the four American state legislatures. Nonetheless, there were differences. Most of these seem explicable in terms of differences in the formal structure and role of the Canadian legislature. Greater emphasis was placed in the Canadian House on channeling controversy into conflict between the parties, and less on rules that expedite the flow of legislation and stress the importance of seniority and apprenticeship. A somewhat larger number of Canadian legislators were unaware of the rules and the sanctions available to enforce them. These differences seem to reflect the fact that the Canadian House is part of a parliamentary system in which party discipline is greater than in the United States; a system where the cabinet is able to control the flow of legislative business; and a system in which seniority is of relatively little importance. The greater ignorance of Canadian members about the rules of the game and

their enforcement may reflect the fact that individual members are less free to define their own jobs in such a setting and play a less significant role, as individuals, in the legislative process. There is thus less need in such a system for effective controls over the behavior of individual legislators by their legislative peers.

Unfortunately, systematic research on the rules of the game in legislatures in other political systems is almost nonexistent. Nathan Leites (1958) has published a valuable study of patterns of legislative strategies in the French Fourth Republic, but it is not directly and explicitly concerned with the normative expectations of legislators and their functions. Gerhard Loewenberg's study of the West German Bundestag (1967) suggests that informal, unwritten rules of the game have developed which have made a formal structure, largely inherited from the Weimar Republic, viable under drastically altered circumstances. But none of these studies permits detailed comparison with the studies conducted in the United States and Canada. Many more cross-nation comparisons need to be made.

A second area of needed research on the rules of the game in legislatures deserves brief mention. Attention so far has been directed primarily at the rules of the game for legislative bodies as a whole. Yet subgroups of legislatures—committees, parties, work groups—sometimes possess relative autonomy and specialized sets of norms which are not identical with those for the whole membership. Richard Fenno's studies of the Appropriations Committee

(1962) and of the Education and Labor Committee (1963) in the U.S. House of Representatives indicate that the payoffs from comparative studies of such legislative subgroups are likely to be large. [See LEGISLATION, especially the article on LEGISLATIVE BEHAVIOR.]

The concept of the rules of the game has, therefore, demonstrated some utility in the empirical analysis of politics. But it is also evident that it overlaps other concepts used in contemporary political science: political culture, norms, ideology, values, strategies, role, and so on. Some of these competing concepts are usually more sharply defined, and in the long run, it therefore seems quite possible that the concept may pass from common use and the game metaphor may be abandoned to the mathematical game theorists. But that time is unlikely to arrive in the near future. In the meantime, the concept serves as a constant reminder of the importance of informal, normative expectations and unwritten rules in shaping political behavior.

#### RUMOR

What are commonly called rumors are those descriptions, forecasts, or explanations of events that are shaped largely in informal encounters and that have not been confirmed by authoritative sources but are, nonetheless, entertained seriously by a substantial portion of an interested collective body. Since the reports are unverified, they may turn out to be either true or false. Although warnings against apocryphal tales can be found in the folklore and literature of many peoples, it is only recently that such tales have become the object of systematic inquiry. Contributions have come from many sources: historians and jurists concerned with the reliability of testimony; psychologists concerned with perception and recall; psychiatrists concerned with the expression of repressed impulses in communicative acts; and sociologists and social psychologists concerned with group problem solving, public opinion, and reactions to disasters. Despite these efforts, comprehension of the phenomenon remains fragmentary, for investigators have faced formidable obstacles in collecting reliable data.

**Two conceptions of rumor.** Pioneering efforts in any field rest on common sense terms, which are vague in reference and contain implicit value judgments, two somewhat different conceptions underlie current studies of rumor. Some regard it as a message that is passed from person to person, assuming that the first speaker in the chain is an eyewitness whose report is accurate and that distortions are introduced in the course of transmission. The basic unit of analysis is the report, and the central problem is to account for its transformation. Since normal communication is assumed to be accurate, rumor is viewed as pathological. Others conceive

of rumor as a summary depiction of an event, a capsule statement that is constructed in the interaction of people who are concerned. For them the unit of analysis is the situation, and the problem is to ascertain how it becomes interpreted. In either case it is useful to distinguish between the *product* and the *process* by which it is shaped.

**Conditions generating rumor.** Investigators are generally agreed that rumors emerge in situations that are inadequately defined—when there has been an unexpected break in the daily routine (the appearance of a stranger), when there is a drastic environmental change (a severe earthquake), when those confronted with alternatives are uncertain of the outcome (an impending election), when people are under sustained tension (a city under siege), or when men performing monotonous tasks become restless but cannot establish the source of their annoyance (rear echelon troops). In each context there is demand for news, although it varies considerably in intensity. When some decision is to be made, any information that might affect the outcome becomes important; once the question has been settled, the sense of urgency wanes, and what had been news becomes history. Ordinarily news is provided by some authoritative source—in modern societies, for example, through the media of mass communication. If demand for news exceeds what is supplied through these channels, interested parties are forced to rely upon one another for information. Thus, any circumstance that hinders the rapid dissemination of news, such as censorship or the physical barriers arising in catastrophes, foment rumors.

Allport and Postman (1947, pp. 33-34) have tried to formalize such observations in their frequently cited formula:  $R \sim i \times a$ ; "the amount of rumor in circulation [R] will vary with the importance of the subject [i] to the individuals concerned times the ambiguity of the evidence [a] pertaining to the topic at issue." Although the exact relationship designated has never been demonstrated, the formula does specify the important variables.

In most communities social contacts are limited by barriers of class, ethnic identity, or other group affiliations, and most rumors are nurtured in well-established informal networks. Festinger and his associates (1948) studied a rumor that a community worker trying to establish a nursery school in a housing project was a communist; they found that 62 per cent of the people with children from one to five years of age had heard it, in comparison to only 28 per cent of the other residents. In an experiment conducted at another housing project, Festinger, Schachter, and Back (1950, pp. 114-

131) planted a rumor that one of the project's special activities was to receive nationwide publicity. They found that this information was conveyed for the most part to individuals who had taken a prominent part in the activity. In disasters, however, information is urgently needed by everyone, and new communication channels emerge spontaneously. One week after the disastrous floods of 1955 a rumor that a dam was about to break sent the populace of Port Jervis, New York, streaming out of the town. In their study of this incident, Danzig, Thayer, and Galanter (see Philadelphia . . . 1958) found that a number of individuals took it upon themselves to broadcast warnings to anyone within range, even though most people turned first to their friends and relatives. During the French Revolution, rumors about brigands employed by aristocrats spread panic through the countryside, and Lefebvre (1932) notes that fugitives, traveling monks, postal carriers, servants sent to warn friends, and local officials all participated in disseminating the alarm. Thus, news is transmitted to persons known to be involved and concerned, and the activation of communication channels varies with the requirements of the situation.

**Content formation.** Although rumors are not necessarily false, neither are they direct descriptions of events. The central problem in the study of rumor is ascertaining how content is formed. This has been approached from three standpoints.

**Experimental studies.** The popular conception of rumor as a message that is passed on from person to person is the basis of experimental studies of serial transmission. The first subject in a series either is asked to describe a picture or is given a predetermined message by the experimenter. He repeats the account to the next subject, who in turn passes on what he has heard. A careful record is made of what happens at each point of contact; additions and omissions are measured. Such studies were first conducted by William Stern in 1902 and have subsequently been repeated by numerous students of legal psychology. The work of Allport and Postman (1947) is the most comprehensive. They summarize their findings in terms of three concepts. Because of *leveling*, the accounts grow shorter, more concise, and more easily grasped. *Sharpening* is the selective perception, retention, and reporting of a limited number of details. *Assimilation* is the tendency of reports to become more coherent and more consistent with the presuppositions and interests of the subjects. Their experiments have been replicated by several others, with substantially the same results; in the course of serial transmission reports become shorter and less

accurate. The conclusion is that rumor content becomes what it is because of faulty perception, limitations of memory, and the inability of most men to repeat, verbatim, complex reports that they have heard.

In spite of the frequent and consistent replications of Allport and Postman's experiments, their conclusions have been challenged by several investigators, who insist that the artificial situation in the experiment differs in important respects from the circumstances under which rumors actually develop. The contention that rumors necessarily become less accurate as they develop has been questioned. In his study of informal communication among American soldiers in the South Pacific during World War II, Caplow (1947) found that many reports became more accurate as they spread. Most men involved in dangerous situations are not gullible; they try to check the accuracy of what they hear, and details that are denied by officials are eliminated. Furthermore, diffusion occurs through a small number of well-defined paths where past rumors had been received with appreciation, and individuals who prove unreliable tend to be eliminated from these networks. Schachter and Burdick (1955) planted a rumor in a girls' school that four students summarily removed from their classroom by the principal were connected with some missing examinations; they likewise found no distortions. On matters in which there is personal involvement, details are not readily forgotten. The contention that rumors necessarily become shorter has also been challenged. Peterson and Gist (1951), who studied the public excitement over the murder of a 15-year-old girl, insist that numerous details accumulate to elaborate a central theme. The prime suspect was believed to be a man who had employed the victim as a baby sitter; and subsidiary reports developed about his absence from the party he was attending at the time of the crime, his relationship with his wife, and other items presumably suppressed by the police. Festinger et al. (1948) also found that various particulars emerged to support the view that the previously mentioned community worker was a communist. Disagreement on this point arises in part from differing conceptions of rumor; individual items may become more concise, but they tend to be supplemented by additional reports. Several studies, then, support Vergil's assertion that *fama crescit eundo*.

*Psychoanalytic approaches.* Psychoanalysts have developed another approach to the problem of rumor content. Since a person taking part in the growth of a rumor can claim he is only passing on

what he has heard, he can speak without assuming full personal responsibility for what he says. This type of activity therefore provides another avenue for releasing repressed impulses. Jung (1910) discusses a rumor, in a girls' school, of sex relations between a teacher and one of the students. The account became disseminated only because of the active participation of a number of students; the girls had similar erotic interests, and the portrayal tapped something that was already "in the air." Distortions are also accounted for in this manner; variations are introduced by participants whose personal needs are slightly different. Rumors take shape, then, as individuals entertain and pass on reports that enable them to give vent to anxieties or hostilities they are reluctant to acknowledge. The method used by psychoanalysts is clinical, but support for their position comes from other studies as well. Allport and Lepkin (1945), for example, found that on the American home front during World War II rumors of waste, special privilege, and corruption in government and in the armed forces were more likely to be accepted by individuals who thought rationing to be unfair or unnecessary, who suffered personal inconveniences from the scarcity of goods, or who had no close friends or relatives in combat zones and were therefore not so personally involved in the war effort.

*Social interaction.* A third approach to the problem of content formation, found largely in the writings of historians and sociologists, is that men who are involved in inadequately defined situations pool their intellectual resources to form reasoned estimates. Rumor is something that is composed in social interaction. Persons deprived of authoritative news speculate about what is happening. They piece together what information they have. Observations are interpreted in the light of what is taken for granted, and the definition that eventually prevails is the one that appears most plausible. For example, rumors developed among German soldiers invading Belgium during World War I that Catholic priests were inciting the populace to commit murder, that machine guns were located in church towers, and that wounded Germans were being mutilated. According to Langenhove (1916), the invaders, who had expected no resistance, were shocked by the guerrilla tactics of the Belgian Army, and reached these conclusions by interpreting events in terms of their conceptions of the French *francs-tireurs* of 1870. Furthermore, as Bysow (1928) points out, rumors tend to become more plausible as they develop. Details that appear incongruent are challenged and eliminated, and

others thought to be relevant are added to make the over-all picture more convincing.

**Patterns of rumor development.** After a comparative analysis of a large number of case studies, Shibutani (1965) concluded that there are several patterns of development. When collective excitement is mild, as in some trivial break in routine, communication occurs through well-established informal networks. Reports are evaluated critically, and the interpretations that are eventually accepted are both plausible and reasonably accurate. On the other hand, when excitement is intense, as in a catastrophe or in the heat of mob action, critical ability is relaxed. New communication channels emerge spontaneously. Rumor content then becomes consistent with the prevailing mood—be it fear, anger, or joy—and men act on the basis of reports that they would question under other circumstances. Rumors are shaped in a selective process, and the basis of selection varies with intensity of collective excitement. Another pattern of development is found in situations characterized by widespread boredom. When demand for accurate information is not urgent, reports are often labeled as rumors and passed on for entertainment by those who do not believe them. These rumors frequently become vehicles for expressing suppressed attitudes.

**Plausibility and consensus.** Before any kind of information can serve as the basis for concerted action, it must be accepted by a substantial portion of the interested public. In many situations people remain skeptical and delay decisions until more authoritative news becomes available; this is especially true of disasters, when many wait until the last possible moment before taking action. Disagreements may arise, and a group may be immobilized. In many cases, however, consensus develops over a rumor. Studies of group problem solving reveal that once a particular view becomes widely accepted, considerable pressure to conform is placed upon those who remain unconvinced. Furthermore, seeing others act on the basis of a rumor tends to make it more credible. Action usually provides an opportunity for reality testing; if there is failure in adjustment, the item is discredited as having been "only a rumor." But many reports are never tested. Beliefs that develop spontaneously in crises are continually being incorporated into the reservoir of popular knowledge to serve as the basis for subsequent judgments.

**Politics and propaganda.** Rumors of all kinds—of secret treaties, troop movements, misdeeds of candidates for public office—have always played an important part in politics; and the problem of

manipulation and control has attracted the attention of scholars. Publicists have sometimes made extravagant claims of successful rumor campaigns, but their contentions are difficult to assess in the absence of independently collected evidence. The propagation of desired rumors is difficult precisely because content does not always remain fixed. News items may be "leaked" into informal networks, but the ultimate product becomes what is plausible to members of the target group. The exploitation of rumors that are already current or the staging of events that lend credibility to them are techniques that have apparently been more successful. During election campaigns and in time of war, there is concern lest opponents sow inconvenient rumors. Denials are usually ineffective, for a rumor does not develop unless it is plausible. Threats of prosecution and other attempts at suppression have also been unsuccessful; indeed, the known existence of censorship tends to create more demand for unofficial news. Appeals for public participation in combating rumors are usually of little avail, although they tend to make people more conscious of the possibility of being deceived. The one procedure that seems to work is the neutralization of sources, for example, the establishment of a conviction that the enemy has a powerful propaganda machine. Then, any inconvenient item can be attributed to the machine and discounted. The techniques of control that actually work are those that rest on principles, in most cases only intuitively recognized, of natural rumor development.

**Explanatory theories.** How are these observations to be explained? For those who regard rumor as pathological, the answer is relatively simple: Accurate communication is precluded by shortcomings of intellect and character of those who make up the links in serial transmission. Most of the other explanatory theories rest on a principle akin to the gestalt law of *Prägnanz*. Prasad (1935, p. 7) writes that as long as a change in the environment remains unaccounted for, there is a distracting sense of incompleteness; this elicits an attempt to understand the new circumstances by completing the incomplete. Allport and Postman (1947, pp. 36–38) declare that a report enjoys dissemination if it permits a "good closure"—if it allows relief from tension, justifies emotions that are unacceptable, or makes the world more intelligible. Festinger (1957) has attempted a more formal statement in his theory of cognitive dissonance; the existence of inconsistency is uncomfortable, and a person will (a) try to reduce it and (b) actively avoid situations and information that are likely to increase it. Rumors, then, are neither the

product of faulty memory nor of efforts to defraud; most of them represent honest attempts to comprehend ambiguous situations.

Although many have been attracted to the study of rumor by concern over accurate communication, the significance of the subject matter extends far beyond this. It adds to an understanding of the local diffusion of materials presented on the media of mass communication. It also reveals the limitations of formal social control. Whenever men distrust official sources, they rely upon one another for news; all authoritarian regimes are plagued by rumors. Furthermore, some of the ways in which popular beliefs develop are disclosed. Those who believe that rational conduct always rests on verified knowledge can acquire a more realistic view of the premises underlying our daily rounds. Since rumor is a form of group problem solving, it is also of importance to students of social change. Far from being pathological, rumor is an integral part of the social process, an important aspect of the continuing efforts of men to cope with the vicissitudes of life.

## RURAL SOCIETY

The scientific study of rural society as a specialized area of sociology is a development of the twentieth century and prior to World War II had its growth principally in the United States. Since 1950 such study has developed institutional support in many countries. The central concern in the sociological study of rural society is with its social organization—the social systems (or subsystems) and their interrelationships within rural society, with urban society, and within the total society. This study has been approached with ecological, cultural, and behavioral emphases. Demographic analysis has had an important place. Some areas of rural sociological analysis are closely related to the concerns of other social science disciplines; for example, settlement patterns with human geography and land tenure with agricultural economics. The adoption and diffusion of technological innovations is one of the areas to which rural sociologists have given special attention.

Sociological investigation of rural society may be classified into four broad categories: studies using rurality as the independent variable; comparative studies of rural societies; studies for which rural society is the setting within which family systems, ecological systems, cultural systems, personality systems, and other phenomena are analyzed; and studies of social change within each of the previous three categories.

A major attempt to generalize on rural-urban differences that are repeated in time and space was made by Sorokin and Zimmerman in 1929, drawing upon the comprehensive compilation of then

existing knowledge and theories and research in European, Asiatic, and American scientific literature represented in *A Systematic Source Book in Rural Sociology* (Sorokin et al. 1930-1932). They hypothesized that the differentiation between rural and urban does not tend to increase perpetually but, rather, that the historical curve of the differentiation shows something similar to a parabolic curve without complete obliteration of all differences (Sorokin & Zimmerman 1929, pp. 608-636).

No comparable comprehensive compendium of the much more numerous and more sophisticated studies completed since the 1920s is currently available. Summarizations for major substantive areas of sociological research are represented for North America by the papers given at the 1961 annual meeting of the Rural Sociological Society (Copp 1964); for the major regions of the world by the papers prepared for the First World Congress for Rural Sociology (1964); and by monographic studies, such as those on the adoption and diffusion of ideas in agriculture (Lionberger 1960; Rogers 1962).

**Importance of rural society.** Despite the ever-accelerating rate of urban growth throughout the world, especially of large cities, since 1800, a majority of the world's population is rural and a majority of the nations of the world have predominantly rural populations. The percentage of the world's population living in localities of less than 20,000 was 97.6 in 1800, 95.7 in 1850, 90.8 in 1900, and 79.1 in 1950 (United Nations, Bureau of Social Affairs, 1957, pp. 111-143). For major world areas, the estimates of the percentage of the population living in places of less than 20,000 in 1950 were: Africa, 91; Asia, 87; Central America, 79; South America, 74; U.S.S.R., 69; Europe (excluding the U.S.S.R.), 65; North America, 58; and Oceania, 53 (Joint UN/UNESCO Seminar on Urbanization in the ECAFE Region, Bangkok, 1956, 1957, p. 98). This percentage decline in rural population has been accompanied by an increase in the number of persons living in localities under 20,000; the estimated number was 1,897.8 million in 1950, compared with 1,460.1 million in 1900. In the majority of the less-developed countries, the rural population has continued to grow in numbers, whereas in the higher-income countries the pattern has varied in recent decades.

The following illustrations use individual countries' definitions of rural and urban. In England and Wales, which became less than half rural by 1851, the equilibrium at about 20 per cent rural maintained since 1921 is associated with some increase in the number of rural residents because the

total population has grown (Saville 1957). In the United States, which became less than 50 per cent rural by 1920 and was 30 per cent rural in 1960, the rural population continued to grow in numbers until 1940 and since then has remained relatively constant, despite the reducing effects of changed statistical procedures. In Brazil, which contains one-third of all the people of the 20 Latin American countries, the percentage rural decreased from 68.8 in 1940 to 54.9 in 1960; at the same time, the number of rural people increased by more than 10 million (Miró 1964). In India, although the urban population has grown at an accelerating rate, 82 per cent of the total population was rural in 1961; the rural population increased by 61 million during the preceding decade, whereas the urban population gained 16 million (Taylor et al. 1965, pp. 104-105). The concentration of rural population in low-income countries and the importance of rural society in plans for economic and social development give added significance to understanding rural society and its interrelationships with urban society.

**The functions of rural society.** The production of food and other raw materials is a basic function of rural societies; indeed, in modern society the survival of the urban sector is dependent upon the effective conduct of this function. Historically, rural society has also functioned as a supplier of people to the city; the relative importance of this rural-to-urban migration is probably greatest in societies that are undergoing modernization. A third distinctive function of rural society is its custodianship of natural resources. Fourth, modern rural societies increasingly serve a residential function for persons with urban-centered sources of livelihood. Finally, in times of societal crisis, there has been a tendency for rural society to perform a "security" function, as represented by urban-to-rural or postponed rural-to-urban migration. In addition, economic functions ancillary to or independent of the primary or "field" activities are characteristically found in rural areas in some form and in some degree but are not considered as distinctive functions of rural society. Rather, the type and extent of these nonprimary functions vary widely among countries and over time.

### The meaning of rural

A uniform definition of the concept "rural" is crucial if sociological analysis is to result in valid generalizations. In the past decade, increased attention has been given to considering the minimum and essential criteria of rural society. Recent research has found that some characteristics once

advanced as attributes of rural society may also be found in the city; close personal primary-group relations are one example. The interchange of people between rural and urban areas through large-scale migration, the influence of urban-centered mass media, greater interdependence of rural and urban economies, and other types of increased systemic linkage are believed to have reduced rural-urban differences. Also, research revealing the diversity within both rural and urban societies has led to a re-examination of the rural concept.

Although there is a broad general consensus that the term "rural" refers empirically to populations living in areas of low density and to small settlements, there are wide variations in the cutting point used operationally to distinguish rural from urban. There is even less agreement on the qualitative attributes that distinguish a rural from an urban community or society. "Rural" has been defined in terms of one or more empirical attributes, as a constructed type with qualitative attributes, and by the two in combination. The methodological and theoretical problems in the definition of the concept "rural" are similar to those in the definition of "urban" and in the use of constructed types in general. Occupational, demographic, ecological, social organizational, and cultural characteristics have all been used as defining attributes.

In the highly influential formulation by Sorokin and Zimmerman (1929), the principal criterion was occupational—the collection and cultivation of plants and animals. They argued that from the agricultural occupation there followed a series of other relatively constant qualitative and quantitative differences between rural and urban communities, most of which were causally connected or interrelated. The use of occupation as the defining criterion for rural society has not found general acceptance by sociologists. Widespread social changes have frequently resulted in farmers living intermingled with residents of the countryside who follow nonfarm occupations at urban places of work, even to the extent that farmers are a minority within their local rural community. Also, the farm operator or members of his household may have a nonfarm occupation. Sociologically, the use of occupation as the criterion leads to a greater interest in the aggregate of individuals than in the properties of a social system.

The most general current practice is to use two demographic variables—absolute size and density of settlement—in defining "rural." In most countries the dividing line between rural and urban is set at population aggregates of somewhere between 1,000 and 5,000 inhabitants. There is a high level

of agreement that the conditions of social action and social organization set by low population density and small size of community have the following effects. First, the pattern of social interaction involves relatively few contacts per individual in a given unit of time and provides relatively little opportunity for personal anonymity; second, there is relatively little division of labor, as there is a restricted range of occupations and a limited variety of social roles; and thus there is relatively little heterogeneity at the community level as compared with urban society. Social roles tend to be more diffuse and less segmentalized, along with being less impersonal. Moreover, social class identification at the community level has a tendency to be based more on ascribed and personal attributes than on general and achieved attributes; from this fact and that of the limited variety of occupational and social roles, it follows that the limits of social mobility are more restricted within rural society. Finally, because of less anonymity, normative deviancy within the rural community tends to be less frequent than in the city.

The evidence that there are universal differences in cultural characteristics associated with differences in density and size is not convincing. An alternative proposal is that "rural" be defined in terms of a particular pattern of value configurations or some other cultural attributes (Bealer et al. 1965). However, since such a construct would make rural society independent of a specific territorial space, it has had little application. Still other suggested criteria for characterizing rural society include: relative size and density rather than arbitrary limits; the ecological notion of relative isolation from or accessibility to larger population centers, expressed by Stewart (1958) in terms of a social network map deriving the proportion of urban contacts from objective indices; and another ecological alternative whereby people engaged in "field" activities would be classed as rural and those engaged in "center" activities would be termed urban. "Field" activities are considered those involving the production of foods, fibers, ores, and raw materials and requiring high man-land ratios (Loomis & Beagle [1950] 1955, p. 204).

The statement by Hatt and Reiss ([1951] 1957, pp. 19–21) that "there are considerable differences among the criteria and the ease with which they can be used in research, the degree to which they provide meaningful theoretical and empirical differentiation, their constancy in time and space, their cultural relativity, and their causal connection or interrelationship" applies to both rural and urban communities. The size and density criteria can be

applied if the focus of analysis of rural society is on demographic variables or on social organization. Dissatisfaction with these two criteria seems to be associated particularly with attempts to generalize about cultural systems, including values, and about personality systems.

The idea of a rural-urban continuum is now generally preferred to a rural-urban dichotomy. In research operations, however, particularly for population analysis, the use of a dichotomy is a common practice. Or, as in the procedure followed by the United States Bureau of the Census, a trichotomy may be set up by dividing the rural into two parts—farm and nonfarm. That the rural-urban continuum concept may need to be reinterpreted is suggested by the Duncan and Reiss finding (1956, p. 40) that, for 11 size-of-community groups, equal differences in the numerical size of two communities were in no case associated with equal differences in the index of any of the population characteristics examined. It may be that unequal rather than equal size-of-community intervals may more closely approximate the threshold of significant differences [see COMMUNITY-SOCIETY CONTINUA].

Within rural society there are wide variations in social organization and in cultural systems. Such types as "primitive," "nomadic," and "peasant" are illustrations. Feudal social organization has been identified as rural and also has been advanced as an ideal type opposed to both rural and urban (Sjoberg 1952). A number of constructed typologies of societies have been formulated, such as "Gemeinschaft-Gesellschaft" and "sacred-secular," which have mistakenly been used as synonymous with rural-urban. Such constructed typologies may, however, be appropriately understood as intersecting the rural-urban typology.

The *traditional-modern* construct, as advanced by Lerner (1958) and adapted by others (Larson & Rogers 1964), seems to have particular promise for the analysis of contemporary rural society. The crucial point here is that members of modern social systems view new ideas more favorably than do members of traditional systems; that is, they differ in their empathic capacity. In addition, modern social systems are characterized by a relatively highly developed technology with a complex division of labor, a high level of literacy and formal education, cosmopolitan social relationships, a relatively large proportion of secondary social relationships, and an emphasis upon economic rationality. Further, the modern society has a high level of development of communication media, which give access to the cumulative pool of knowledge of the larger society and provide a comparatively high

degree of linkage and articulation among the subsystems in relation to the societal system.

### Social change in rural society

The trend toward modernization of traditional rural societies, which has been under way for well over a century in North America, Great Britain, and western Europe, has accelerated and become more pervasive during the twentieth century, especially since World War II. Rural societies of the modern type are so interlinked with their national systems and the international system that the changes in their social organization are highly similar in many respects. Traditional-type rural societies are generally moving toward the same type of linkage. The process by which a traditional, largely isolated and segmented, rural society becomes a modern-type rural society integrated with the national society is a special case of the more general process of societal change.

Although there are complex theoretical and methodological problems involved in the analysis of social change, there is considerable agreement about the direction and universality of major changes that have been under way in social and cultural systems. These major changes have been expressed in such highly general terms as increased structural differentiation, or specialization, of social systems; more universalistic norms; and the growth of a rational orientation (Moore 1963; Parsons 1964). This discussion of social change will focus on the following selected factors, which have special significance for the rural social changes of the present century: the growth and application of technological and scientific knowledge; the increase in urbanization; the growth of the money-and-market economy; and the increase in purposive innovation, reflecting rationality and a favorable attitude toward change. These factors may operate partly independently and partly in association and may be in part and in some ways circular in their effects. In large measure, they operate generally as external forces for change in rural societies and their social systems. The changes which these forces generate within rural communities in turn produce additional internal community changes.

Empirical data for use in describing the current situation, measuring changes, and making comparative studies are most adequate for the more modern rural societies, such as those in North America, western Europe, and Japan, but even for these there are major deficiencies. In general, the available information on the rural societies of the world is less complete regarding social organization and the different categories of social systems than

it is for population, technology, physical resources, and production, although these data may be reflective of social organization variables.

**Technological and scientific advances.** Agricultural production technology offers some of the most dramatic examples of the social consequences of technological change through major innovations and improvements (Moore 1963, p. 77). The extent to which technological advances and science-based practices have been diffused and adopted varies widely from country to country. Even in the most modernized nations, survival of traditional methods may be found in some local areas. It is estimated that about 90 per cent of the power used on the world's farms is still supplied by human beings and animals.

In 1953 the Woytinskys estimated that more than half of the world's labor force was engaged in agriculture (Woytinsky & Woytinsky 1953, p. 364). The proportion so engaged ranged from about 5 per cent in a modernized food-importing nation, such as Great Britain, to more than 80 per cent in more traditional societies. The general trend is for the proportion of the labor force engaged in agriculture to decline; for example, in the 20 Latin American countries the percentage fell from 61 in 1936 to 47 in 1960 (United Nations, Economic Commission for Latin America 1964, p. 23). The percentage decline may be accompanied by an increase in the number of persons in agriculture, as in Latin America, or by a decrease, as in the United States.

The effects of the application of technological and scientific knowledge in the rural sector of a modern society can be seen in the United States. Trend data for 1870-1960 show that productivity per worker in agriculture and per man-hour increased rather regularly at slightly less than 1 per cent per year until the mid-1930s, after which it increased at the accelerated rate of 4 to 5 per cent annually (Meiburg & Brandt 1962). Between 1940 and 1959, while total farm production increased by 52 per cent, the proportion of land allocated for farming and the number of harvested acres changed only slightly and the number of farm workers and aggregate man-hours of farm work declined to less than half of the peak reached prior to 1920 (Larson & Rogers 1964). The farm population correspondingly declined to less than half of its peak number and became a minority within the rural population. Increased worker productivity was accompanied by fewer but larger farms. The number of farms per 1,000 acres of land decreased from 7.5 in 1880 to 3.3 by 1959. Such a reduction led to a decrease in population density in all areas

where farm population losses were not offset by growth of the rural nonfarm population. At the local level, the territoriality and size conditions for many rural social systems were changed as a consequence of the series of changes in farming.

Modern transportation has served to increase the frequency of rural-urban interchange and to facilitate the use by rural people of a network of centers with specialized functions. Technological developments in communication also have a major influence in the modernization process by greatly enlarging and facilitating access to the pool of knowledge. They support the linkage of the rural community and its subsystems into a network of systems that may cross national boundaries, support centralization of decision making, foster a broader "world view" on the part of the rural resident, and change the nature of the interaction process in communication from oral, direct, and two-way to mediated or one-way. For example, the adoption of radio has been rapid since 1950, even in the isolated areas of the more traditional societies (United Nations, Bureau of Social Affairs, 1957, p. 79). The mass media are largely urban centered and urban controlled, extending their influence without requiring the rural resident to make physical contact with the city. To date, studies of the diffusion of new ideas that may be adopted by individuals voluntarily, such as farm practices, indicate that the mass media are important in creating awareness and interest but that personal contacts are a more important information source at the adoption stage (Bohlen 1964, pp. 281-283). Furthermore, different types of adopters make differential use of mass media; the innovators make the most use of it, whereas the slow adopters place more reliance on personal and primary-group information sources.

**Urbanization.** In recent decades the rate of urbanization has been declining in the more modernized societies, where urbanization is now greatest, and generally increasing in more traditional rural societies. In the latter, the rapid urban expansion not only reflects the normal "pull" factors but also is the consequence of powerful "push" factors in rural areas with heavy population pressure on land resources and limited nonagricultural development (United Nations, Bureau of Social Affairs, 1957, pp. 124-125). The extent to which a high level of urbanization may provide an outlet for excess rural population is suggested by the estimate of Beale et al. (U.S. Department of Agriculture, Economic Research Service, Economic and Statistical Analysis Division, 1964a) that as of 1958 in the United States about 63 per cent of the farm-born adults were nonfarm residents.

Net rural-to-urban migration is selective as to who leaves and who remains. Migration to cities tends to select young adults, although there may be instances where such selectivity does not hold (Davis & Golden 1954-1955). Generally, in the more modernized societies relatively more females than males migrate from rural areas; in the more traditional societies, more males leave. However, there are exceptions to this sex selectivity pattern. In a country as modernized as Japan, relatively more rural males than females go to the city; whereas in the Latin American countries, rated as more traditional on the whole, the opposite holds true.

**Money-and-market economy.** The Woytinskys estimate that in the world as a whole not more than one farmer in five is engaged in commercial farming, producing largely for the open market; the balance are subsistence farmers, producing mainly to meet their own needs (Woytinsky & Woytinsky 1953, p. 452). In the countries with more traditional societies where Western colonization occurred, the development of large-scale commercial agricultural production and exploitation of mineral and oil resources for the world market has produced a form of dual economy [see ECONOMY, DUAL].

In the modernized societies the money-and-market economy puts a premium upon rationality and efficiency, which has led to increased specialization of agricultural enterprises by areas and by individual farmers, an increased reliance on purchased inputs in farm production, the development of new types of credit systems for farmers, the growth of farmers' marketing and purchasing co-operatives, and major changes in the marketing system for farm products.

**Planned change.** During the present century, and especially during the past two or three decades, national governments have had a conspicuous role in beginning innovations. The United Nations complex of international organizations and such regional arrangements as the Organization of American States, as well as the United States—and more recently a few other national governments—have developed extensive programs aimed at helping the underdeveloped nations to speed up the modernization of their traditional rural societies. Practically all nations with quite modernized rural societies have undertaken a wide range of activities to equalize social conditions. Illustrations are price and income support programs for farmers, the development of infrastructure (improved roads, electric power lines, telephones, and water supply systems), rural mail delivery, improvement of rural

educational facilities, and special programs for library service, medical care, and hospitals. Action for the purpose of maintaining and strengthening the national system ranges from relatively limited land reform, resettlement, and land consolidation in such countries as Italy, the Netherlands, and Sweden to attempts at inclusive restructuring of rural society in the U.S.S.R. and mainland China.

In at least the more modern societies, the net effect of these and related factors is to bring several of the social systems of which rural people are members under heavy pressure to restructure, both horizontally and vertically. The rise in standards and levels of expectation shared by rural people affects both "public" and "private" systems. Realignments are required in order to provide the necessary population and financial base for supplying the more specialized services at reasonable cost. Thus, the territoriality of systems providing education, health care, local government, and numerous economic functions for rural people is under strain to readjust to the patterns made possible by new transportation technology. The reduction of the number of public school districts in the United States from 127,000 in 1932 to 49,000 in 1958 through consolidation is illustrative (R. M. Williams 1964, p. 23). There is an over-all trend toward mutual interdependence among locality groups, with different functions located at different centers, with rural families using a number of centers for services, and with each type of economic and social service tending to have its own unique service area. An increase in the heterogeneity of the rural community results from the decrease in the percentage of the population engaged in farming or in other "field" activities, the separation of place of work from residence for the commuting nonfarm workers whose employment is outside the community, and—in some instances—the increase in seasonal residence by urban dwellers.

Urban-centered and rural-centered systems are increasingly in contact, either cooperating formally or informally with greater systemic linkage or in conflict to maintain system boundaries. Urban expansion puts especial pressure on rural areas at the growing edge of the city.

Many of these social changes occur unevenly, even within countries. There tend to be regional differences, community differences, and variations by class status and by culturally deviant groups. Rural communities with expanding populations have been shown to have adjustment problems different from those with stable or declining populations (Larson & Lutz 1961).

Ecological spatial relationships possess a considerable degree of built-in structural stability; land use, field, and settlement patterns are not easily changed (W. M. Williams 1964). Outside the areas of wholesale land reform or new colonization, the spatial arrangements in rural areas have changed more slowly than technology or some of the social systems. However, there have been several notable ecological changes: land consolidation programs and limited transfer of farmers from villages to dispersed farms in western Europe; enlarged farms generally and some shift of farmers to villages in the Great Plains wheat belt of the United States; and the thickening of settlement within the commuting area of urban centers.

### Contemporary rural-urban comparisons

The pattern of higher fertility in rural than in urban areas is observed in practically all countries for which data are available, although it seems generally to be least marked within the most traditional societies. The differentials have been persistent, even in the more modernized nations. In 1960, the number of children ever born per 1,000 rural women aged 35-39 years in the United States was more than one-fifth larger than for urban women; in none of the 50 states was the urban fertility as high or the average size of family as large as the rural (U.S. Department of Agriculture, Economic Research Service, Economic and Statistical Analysis Division, 1964b). Because of the heavy out-migration of the rural born, the annual rate of growth is higher for the urban than for the rural population in nearly all nations for which data are available for the most recent decades.

The combined effects of differential fertility and differential migration leave the rural areas with a disproportionate burden of dependents, especially children, and a relative shortage of persons in the productive adult years. With the exception of certain Asian and African countries, rural areas have more males than females—particularly at the younger adult ages—because of the selective factor in net migration. These differences in sex ratios reflect the difference in work roles. In the most modernized countries, the greatest opportunity for gainful employment for females is in nonfarm work; the "field" activities are predominantly men's work.

In a modern society, the rural-farm sector is the only one in which place of work, place of residence, occupation, and family are so tightly wrapped together. Sorokin and Zimmerman's generalization (1929, p. 334) that the rural family is more stable than the urban family has been supported by some

recent studies in the United States (see Burchinal 1964, pp. 177-178). However, in some instances, as for Panama and Venezuela in 1950, a significantly higher proportion of consensual unions exist in rural areas (Miró 1964). That role performance by sex and age differs between rural and urban families in some respects is suggested by research on the United States; however, according to Burchinal (1964), there is evidence that rural and urban family organizations in the United States are becoming more alike.

There are major gaps in comparative rural-urban cross-national research on most of the social subsystems and particularly in group-level research that uses the concrete social system—such as the school or the church—as the unit of analysis. However, to some extent, inferences about these systems may be derived from the more available demographic, occupational, and similar census-type and aggregate data. The high association of illiteracy with rurality in national comparisons and the fact that the pattern of fewer years of school completed by rural adults has persisted in a nation such as the United States suggest rural-urban differences in the systems of formal education. The evidence shows quite consistently that, at a minimum, educational and other social-service type systems in rural areas tend to be smaller in size and less specialized in function. The extent of the structural influence of the conditions for social action in rural society is hinted at by research showing that youth clique groups are smaller in rural than in urban areas (Hare 1962, p. 225).

The occupational influence of agriculture contributes to the persistence of distinctive characteristics in rural society. The alliance of occupation, residence, and family has already been noted. In addition, although there are areas where large estates, concentrations of ownership, or large-scale state or collective units may be found, farming generally is characterized by small units of operation, with the management and worker roles combined in the farmer and with the work performed primarily by the farmer and members of his family; so the ratio of independent to other workers is in sharp contrast to that in the nonagricultural pursuits. Occupational self-recruitment is greater for farming than for the other major occupational categories; that is, a higher percentage had fathers in the same occupation. Finally, studies covering both Western and non-Western countries, some over several decades, show that income of farmers is consistently and persistently below that of nonfarmers (see Bellerby 1956).

A number of studies have shown that demo-

graphic, occupational, and economic factors have a gradient pattern in relation to large urban centers, varying quite consistently with distance. Thus, the youth dependency ratio and the fertility ratio in the white rural-farm population rose regularly and consistently with increasing distance from the nearest standard metropolitan statistical area in the United States in 1960 (Beegle 1964).

Rural-urban differentials in modernized societies have been greatly reduced or even eliminated in many respects. Although an increase in cultural homogeneity is suggested, differences in social organization persist. The several theories about community growth, center functions, and social differentiation generally support the proposition that the conditions of social action result in the persistence of rural-urban differences in scale and complexity over a wide range of social systems. Purposive action is directed at minimizing the differences in those systems vested with public concern.

## RUSH, BENJAMIN

Benjamin Rush (1746-1813), American physician, politician, and social reformer, was born in Byberry, Pennsylvania, the son of a farmer and gunsmith. After graduating from the College of New Jersey (later Princeton) in 1760, he was apprenticed to the physician John Redman. He entered the University of Edinburgh in August 1766 and received his medical degree in June 1768, after presenting a thesis, *De coctione ciborum in ventriculo*, based on several experiments performed on himself and a friend. Shortly after his return to Philadelphia in 1769, Rush was elected professor of chemistry in the College of Philadelphia (now the University of Pennsylvania) and began the practice of medicine.

Like his contemporaries Franklin and Jefferson, Rush was a representative of the American Enlightenment. As a republican, he was an ardent proponent of American independence. In 1776 he was made a member of the Continental Congress and signed the Declaration of Independence. He joined the Continental Army in December 1776 and from April 1777 to January 1778 served as surgeon-general of the armies of the Middle Department. But differences arose between Rush and William Shippen, the director-general, which led to Rush's resignation and resumption of private practice in Philadelphia. In 1789 he was appointed professor of the theory and practice of medicine in the medical faculty of the College of Philadelphia.

At the same time Rush continued his social and political activities. He felt obliged to use his mind and pen in any way that would advance national unity and foster political stability in the young American republic. Thus, he advocated the national constitution of 1787 and helped to frame the Pennsylvania state constitution of 1790. From

1797 to 1813 he served as treasurer of the United States Mint. Moreover, recognizing the relationship between an informed public opinion and popular sovereignty, Rush saw the need to prepare the citizens for the task of governing. Consequently, he advocated a national system of education, with various state-supported schools, including a national university and technical schools. In addition, Rush also championed higher education for women, and he was largely responsible for the founding of Dickinson College in western Pennsylvania.

But Rush's efforts for the public good went beyond education. His major impulsion to action arose from the desire to improve the conditions of men in a rational manner. He was an early and passionate proponent of the abolitionist cause, serving as president of the Pennsylvania Society for Promoting the Abolition of Slavery. He advocated temperance and legal control of drinking. Penal reform was another cause that Rush made his own, and in 1787, together with Franklin and several like-minded men, he organized the Philadelphia Society for Alleviating the Miseries of Public Prisons. It was this group that succeeded in having the death penalty in Pennsylvania abolished for all crimes except murder in the first degree. Rush was likewise a principal founder, in 1786, of the Philadelphia Dispensary for the Poor, the first free dispensary in the United States.

As a physician, Rush, like so many of his medical contemporaries, is a characteristic figure of the transitional period during which modern medicine was just beginning to emerge. Medical practice was based on empiricism, tradition, and theories that lacked any firm scientific foundation. Moreover, like other physicians of his time, Rush supported his opinion and practice by argument rather than experiment.

Rush's most significant contribution to medicine and to social welfare was his study of mental illness. In 1812 he published *Medical Inquiries and Observations Upon the Diseases of the Mind*, the first American treatise on mental illness. It remained the only American work of its kind for more than fifty years after its publication. Basing his treatise on observations made at the Pennsylvania Hospital, where he was in charge of mental patients for some thirty years, Rush attempted to provide a systematic account of mental disorders in terms of theory and practice. He viewed mental derangement as basically due to disease of the cerebral arteries, and his therapy was intended to relieve this pathology. Treatment was designed to affect the circulation of the blood and included purges, emetics, bleeding, a bland diet, and hot

and cold showers. At the same time, Rush was aware of psychic components in mental illness and urged the patients to write down what troubled their minds and to read what they had written. It is clear that he was aware of the ill effects of repressed emotions. Rush was humane to his mental patients, but he recommended coercion under some circumstances and even advocated corporal punishment in extreme situations. Like his contemporary Philippe Pinel, Rush knew the importance of enlightened hospital management in dealing with mental patients. It was due to his efforts that a separate wing for the insane was added at the Pennsylvania Hospital in 1796. Rush likewise recognized the need for well-qualified persons to serve as attendants in establishments for the mentally ill, as well as the necessity of keeping the patients and their quarters as neat and clean as possible. He also advocated occupational therapy; the separation of those patients who were disoriented and violent from the others; the provision of exercise and recreation for the patients; and the treating of the mentally ill with respect and kindness.

Rush exerted a significant influence on the practitioners of his time and for several generations after his death. His most important achievement was his pioneer endeavor to raise the study and treatment of the mentally ill to a systematic, scientific level.

## SAINT-SIMON

Claude Henri de Rouvroy, Comte de Saint-Simon (1760–1825), French social philosopher and reformer, is a controversial figure in modern social thought, who—without writing a single enduring work—had a crucial role in the early nineteenth-century developments of industrial socialism, positivism, sociology, political economics, and the philosophy of history. In his final years he inspired a Christian socialist movement with a secular gospel of human brotherhood. By scholarly standards his works—mostly reformist essays and brochures—are highly deficient: overly polemical, weak in organization and conceptual clarity, and often marred by confusions between questions of value and fact. Much of his subsequent influence is due to students and disciples, who systematized, popularized, and also partly reshaped his ideas, and especially to Auguste Comte, his onetime protégé and collaborator, whose work in sociology and philosophy greatly overshadows Saint-Simon's.

In retrospect, Saint-Simon's main significance for the social sciences is threefold. He was one of the first to grasp the revolutionary implications of "industrialization" (a word he himself coined) for traditional institutions and morality and to conceptualize the industrial system as a distinctive type. He was also among the earliest to advocate a naturalistic science of society as a rational guide to social reconstruction. But he is most important as provisional formulator of an "evolutionary organ-

icist" theory, whose influence is reflected in social evolutionary doctrines as diverse as those of Herbert Spencer, Lester Ward, and Karl Marx. He directly inaugurated the "positivist organicist" school—most notably represented by Comte and Émile Durkheim—which for a century thereafter was to vie with utilitarianism, Marxism, and Hegelian historicism for theoretical predominance in the social sciences (Martindale 1960, part 2). Through Durkheim, his organicist concept of social order carries over into contemporary "functionalism" in anthropology and sociology.

Recent biographers have depicted Saint-Simon as a brilliant, but erratic, figure, possessed from early life with a consuming passion for greatness which led him into various endeavors, turning to serious studies and his writings after the most varied social experiences. He was born in Paris to the socially marginal, relatively impoverished side of a prominent noble family that claimed descent from Charlemagne. His boyhood education, through tutoring, included conventional exposure to Enlightenment ideas and Catholicism, both profoundly influential in his later thought. At 17 he was commissioned into the army, remaining for four years, during which he fought with some distinction in the American Revolution. From this time until the French Revolution he tried a variety of ambitious promotional ventures with little success. During the Terror of 1793–1794 he was imprisoned for a year, narrowly escaping a death sentence. This experience left him with a lasting dread of revolutionary violence. After his release, he amassed a considerable fortune—by speculating in confiscated church lands—which he lavished on an extravagant Paris salon, catering particularly to scientists and intellectuals, from whom he ac-

quired a broad, if superficial, education. But his funds were spent by 1804, and he lived his last twenty years in modest circumstances, at times verging on poverty, largely cut off from his former glittering life.

### Social theory

At 42, with poverty threatening, Saint-Simon took up his new career as writer and social reformer. Throughout the turbulence of the Napoleonic empire and the Bourbon restoration, he presented a many-sided analysis of problems confronting Europe, proposing numerous remedies that gradually broadened into a full-scale social reconstruction program. The emphasis shifts at several points, and few of the ideas, taken singly, are new. What is new is the underlying rationale of evolutionary organicism: a partly conscious synthesis of the scientific naturalism and rationalist faith of Condorcet and the Enlightenment, the more practical materialism of the rising entrepreneurial bourgeoisie; and the authoritarian emphasis upon ideological unity found in Burke and in restorationists like Bonald and de Maistre.

The starting point is the conservative ideal of "organic" equilibrium, according to which society is unified under a single organizational system, undisturbed by conflicts between individuals or social classes. To Saint-Simon such integration requires both a "temporal" system of institutions (for government, the economy, and other coordinative activities) and a "spiritual" ideology of worldly existence and conduct that would give coherent justification to the temporal system and command the allegiance of the highly educated as well as the general populace. Under such an established order, individuals are viewed as beholden to the system for survival and well-being, and a mutual interest of all social classes in the system's success is assumed.

Conservative versions of organicism had generally accepted a single equilibrium state with traditional sanction. Saint-Simon was among the first to relativize organicism by adding the evolutionary idea of social development. He conceived of an orderly progression of stable organic civilizations that represent different stages of advancement. Each system in turn is viewed as appropriate to its time of formation, only to become obsolete as a higher level is reached. Thus, in the history of Western man, Saint-Simon discerned two main organic systems. The first, predominant in ancient Greece and Rome, had a polytheistic ideology, a slave economy, and monolithic political rule. By

the eleventh century, it had been supplanted by the second, characterized by feudalism and Catholicism, after centuries of disorganization and conflict between the two rival systems. The triumph of medievalism was assured by its superiority over its predecessor in promoting a more rational theology, a more humane form of bondage, the separation of temporal from spiritual power, and technological improvements. In this analysis, Saint-Simon, like the Enlightenment philosophers, accepted the growth of knowledge and ethical understanding as primary criteria and determinants of evolutionary progress. He posited a broad, overriding trend in human history, from anthropomorphically theistic interpretations of the world to scientific naturalism, and, correlatively, from domination by the strong to productive cooperation and humane morality. As enlightenment progresses, new civilizations are formed, based on new ideologies initially introduced by advanced elites and subsequently reflected in popular institutions. But the transition from one system to another is very slow, since organic civilizations require centuries to develop and, once established, are strongly resistant to change.

Saint-Simon believed that all Europe had been in a transitional crisis since the fifteenth century, when medievalism began to give way to a new system founded on industry and science. He wrote as the new system's advocate, urging heads of state and influential groups to hasten its inception as the only way to restore stability; he was, thus, the first of many meliorists to present reforms as evolutionary necessity ("Our intention merely is to promote and explain the inevitable."). His early writings during Napoleon's reign stress ideological aspects of the crisis and contain his main positivist doctrines (1807; 1813a; 1813b). The groundwork of positivism as an empiricist philosophy of knowledge had already been established by Bacon, Hume, and others. Saint-Simon's contribution, later amplified in Comte's more rigorous work, was its evolutionary reformulation as part of a comprehensive reconstruction program. He argued that theistic Roman Catholicism—the spiritual basis of medievalism—had been undermined by the sciences and by such secularists as Voltaire and the Encyclopedists. But these modern intellectual forces, while aiding progress by exposing an outdated system, had been negativistic in failing to provide an adequate replacement. Needed, instead, was a new, encompassing "positive" philosophy based on the sciences, as fundament for the new social order. All sciences were to contribute, including a new

social science (called social physiology, to indicate that social phenomena were to be viewed as part of life's natural development) that would "inductively" derive the new moral codes and policies for the future society by historical extrapolations—a task for which no explicit methodology was offered. A new scientific advisory group would insure the application of results to social policy, so "that men henceforth [would] do consciously and more effectively what they previously [had] done slowly, unconsciously and indecisively" (*Oeuvres de Saint-Simon*, vol. 18, p. 166). Popular attitudes were to be correspondingly changed by a scientific program of mass education that would eventually establish a nontheistic religion of "physicism." Thus, Saint-Simon envisioned nothing less than a total scientific transformation of Western civilization and implied that while positivism would serve as a new philosophy for the educated, it would function as a religion for the masses.

After Napoleon's downfall Saint-Simon shifted his attention from the ideology of the new system to its temporal structure and policies. In a series of periodicals, *L'industrie* (1816–1818), *Le politique* (1819), *L'organisateur* (1819–1820), and *Du système industriel* (1821–1822), he supported the third estate against the re-established nobles and clergy. These periodicals contained many of his own articles presenting his main socialist doctrines—but a strange socialism it is, resembling venture capitalism and technocracy as much as Marxism or primitive communism. In contrast with the latter, he abandoned the ideal of the small equalitarian communal unit, still partly upheld by Fourier and others. The future society portrayed is, above all, one of productive achievement, with poverty and war eradicated through bold, large-scale industrialization under planned scientific guidance. It is an open-class system in which caste privileges are abolished, work is provided for all, and rewards are assigned according to merit. The state changes from "government" (characterized by class domination and national rivalries) to a welfare system managed scientifically by expert public servants who are mainly concerned with economic regulation; the power of the state is drastically reduced, and what is left is transferred from war lords and idlers to the productive workers. But, unlike Marx, Saint-Simon opposed all violence, whether revolutionary or not, hoping that the feudal rulers would relinquish their power peacefully as they became persuaded of their fate. He also differed from Marx in viewing bourgeoisie, scientists, and proletariat alike as members of the

productive working class: all are natural allies in the struggle against feudalism and cobeneficiaries of the future industrial system. In fact, he saw bankers, engineers, and manufacturers (under scientific advisement) as the best qualified revolutionary leaders of the working-class coalition and hoped that, through their managerial effectiveness and wisdom, destructive class struggles would disappear in the future. The most basic contrast, however, is that despite Saint-Simon's emphasis on material prosperity as a political goal, he was more an ideological than an economic determinist. The desired evolution ultimately depends, for him, on the enlightened good will of those in power, and to foster this good will, in his final work, "New Christianity" (1825), he espoused a secular Christian revival that would instill in all social classes an awareness of their common destiny.

### Influence

Saint-Simon's ideas caused little stir until his death, when a movement was formed in his name, inspired by "New Christianity" and propounding a gospel of brotherly love, concern for the poor, and the reconciliation of spiritual values with material progress. During eight stormy years of organized existence, it attracted surprisingly many of Europe's outstanding young intellectuals (at various times including Carlyle, Mill, Buchez, Carnot, Blanc, Chevalier, and Heine, to name only a few) by appealing to a rising discontent with capitalism and a sense that reform was needed. First led by Bazard, the movement reworked Saint-Simon's ideas into the famous *Doctrine of Saint-Simon* (1830; often dubbed socialism's "Old Testament"), for which he is best remembered. But while the doctrine retained and made more coherent Saint-Simon's evolutionary formula, concept of crisis, stress on planning, pacifism, work ethic, and call for restored social unity, it also introduced important changes. In a position closer to Marxism, it condemned capitalist exploitation along with feudalism; abolition of inheritance, socialization of property, and equality of the sexes were all added to the program; the whole approach became more authoritarian and antiscientific in spirit. This trend came to a climax in 1832, after a bitter schism in which, under Enfantin's charismatic direction, one faction of Saint-Simonians became a hierarchical religious sect, complete with mystical liturgy, substituting a sensate monism of flesh and spirit for the remnants of scientific empiricism. Enfantin quickly fell into disrepute for attacking marital "hypocrisy" and advocating "free love" (which

Saint-Simon himself had indulged in but never preached), and the sect was disbanded for its heresies; but not before its earlier doctrine had become a part of the intellectual heritage of the West.

#### WORKS BY SAINT-SIMON

The periodicals edited by Saint-Simon, *L'Industrie* (1816-1818), *Le politique* (1819), *L'organisateur* (1819-1820), and *Du système industriel* (1821-1822), are often catalogued by libraries under Saint-Simon's name. Manuel 1962 describes them as appearing intermittently, in part to evade the rules of censorship applied to serial publications, but chiefly because Saint-Simon found it difficult to raise the money necessary to publish them.

1807 *Introduction aux travaux scientifiques du dix-neuvième siècle*. Paris: Scherff.

(1813a) 1876 *Mémoire sur la science de l'homme*. Volume 40 of *Oeuvres de Saint-Simon et d'Enfantin*. Paris: Dentu.

1813b *Travail sur la gravitation universelle*. Paris. → No publisher given.

(1825) 1952 *New Christianity: Dialogue*. Pages 81-116 in Saint-Simon, *Selected Writings*. Edited and translated by F. M. H. Markham. Oxford: Blackwell. → First published in French. A new French edition was published in 1943 by Aubry.

*Henri de Saint-Simon: Social Organization*. New York: Harper, 1964. → Also published in 1952 by Macmillan under the title *Henri de Saint-Simon: Selected Writings*.

*Oeuvres de Claude-Henri de Saint-Simon*. 6 vols. Paris: Éditions Anthropos, 1966. → Volumes 1-5 reprinted from *Oeuvres de Saint-Simon et d'Enfantin*, 1865-1878. Volume 6 reprinted from other works.

*Oeuvres de Saint-Simon et d'Enfantin*. 47 vols. Paris: Dentu, 1865-1878. → Saint-Simon's writings are in Volumes 15, 18-23, and 37-40.

*Selected Writings*. Edited and translated with an introduction by F. M. H. Markham. Oxford: Blackwell, 1952.

## SAMPLE SURVEYS

There is hardly any part of statistics that does not interact in some way with the theory or the practice of sample surveys. The differences between the study of sample surveys and the study of other statistical topics are primarily matters of emphasis.

The field of survey research is closely related to the statistical study of sample surveys [see SURVEY ANALYSIS]. Survey research is more concerned with highly multivariate data and complex measures of relationship; the study of sample surveys has emphasized sampling distributions and efficient design of surveys.

### I. THE FIELD

W. Edwards Deming

### II. NONPROBABILITY SAMPLING

Alan Stuart

## I

### THE FIELD

The theory of sample surveys is mathematical and constitutes a part of theoretical statistics. The practice of sample surveys, however, involves an intimate mixture of subject matter (such as demography, psychology, consumer research, medicine, engineering) with theory. The germ of a study lies in the subject matter. Translation of a substantive question into a stimulus (question or test) enables man to inquire of nature and to quantify the result in terms of estimates of what the same inquiry would produce were it to cover every unit of the population.

Sampling, properly applied, does more. It furnishes, along with an estimate, an index of the precision thereof—that is, a margin of the uncertainty, for a stated probability, that one may reasonably ascribe to accidental variations of all kinds, such as variability between units (that is,

between households, blocks, patients), variability of the interviewer or test from day to day or hour to hour, variations in coding, and small, independent, accidental errors in transcription and card punching.

The techniques of sampling also enable one to test the performance of the questionnaire and of the investigators and to test for differences between alternative forms of the questionnaire. They enable one to measure the extent of under-coverage or over-coverage of the prescribed units selected and also to measure the possible effects of differences between investigators and of departures from prescribed rules of interviewing and coding.

This article describes *probability sampling*, with special reference to studies of human populations, although the same theory and methods apply to studies of physical materials, to accounting, and to a variety of other fields. The main characteristic of probability sampling is its use of the theory of probability to maximize the yield of information for an allowable expenditure of skills and funds. Moreover, as noted above, the same theory enables one to estimate, from the results themselves, margins of uncertainty that may reasonably be attributed to small, accidental, independent sources of variation. The theory and practice of probability sampling are closely allied to the design of experiments.

The principal alternatives to probability sampling are judgment sampling and convenience sampling [see SAMPLE SURVEYS, *article on NON-PROBABILITY SAMPLING*].

**Uses of sampling.** Probability sampling is used in a wide variety of studies of many different kinds of populations. Governments collect and publish monthly or quarterly current information in such areas as employment, unemployment, expenditures and prices paid by families for food and other necessities, and condition and yield of crops.

In modern censuses only basic questions are asked of every person, and most census information is elicited for only a sample of the people, such as every fourth household or every twentieth. Moreover, a large part of the tabulation program is carried out only on a sample of the information elicited from everyone.

Sampling is the chief tool in consumer research. Samples of records, often supplemented by other information, furnish a basis on which to predict the impact that changes in economic conditions and changes in competitive products will have on a business.

Sampling is an important tool in supervision and

is helpful in many other administrative areas, such as studies of use of books in a library to improve service and to make the best use of facilities.

**Sampling—what is it?** Everyone acquires information almost daily from incomplete evidence. One decides on the basis of the top layer of apples in a container at the fruit vendor's whether to buy the whole container. The top layer is a good sample of the whole if the apples are pretty well mixed; it is a bad sample and may lead to a regrettable purchase if the grocer has put the best ones on top.

The statistician engaged in probability sampling takes no chances on inferences drawn exclusively from the top layer or from any other single layer. He uses random numbers to achieve a standard degree of mixing, thereby dispersing the sample throughout the container and giving to every sampling unit in the frame an ascertainable probability of selection [see RANDOM NUMBERS]. He may use powerful techniques of stratification, ratio estimation, etc., to increase accuracy and to decrease costs. For instance, in one type of stratified sampling he in effect divides the container of apples into layers, mixes the apples in each layer, and then takes a sample from each layer.

**Some history of sampling.** Sir Frederick Morton Eden estimated the number of inhabitants of Great Britain in 1800 at nine million, using data on the average number of people per house in selected districts and on the total number of houses on the tax-rolls, with an allowance for houses not reported for taxation. The first census of Great Britain, in 1801, confirmed his estimate. Messance in 1765 and Moheau in 1778 obtained estimates of the population of France by multiplying the ratio of the number of inhabitants in a sample of districts to the number of births and deaths therein by the number of births and deaths reported for the whole country. Laplace introduced refinements in 1786 and calculated that 500,000 was the outside margin of error in his estimate of the population of France, with odds of 1,161 : 1. His estimate and its precision were more successful than those of the complete census of France that was attempted at the same time. [See LAPLACE.]

A. N. Kiaer used systematic selection in a survey of Norwegian workers in 1895, as well as in special tabulations from the census of Norway in 1900 and from the census of Denmark in 1901 and in a study of housing in Oslo in 1913.

Bowley in 1913 used a systematic selection of every twentieth household of working-class people in Reading (England) and computed standard errors of the results.

Tabulation of the census of Japan in 1921, brought to a halt by the earthquake of 1923, went forward with a sample consisting of the records of every thousandth household. The results agreed with the full tabulation, which was carried out much later. The Swedish extraordinary census of 1935 provides a good example of the use of sampling in connection with total registrations.

One strong influence on American practice came in the 1930s from Margaret H. Hogg, who had worked under Bowley. Another came when controversies over the amount of unemployment during the depressions of 1921 and 1929 called for improved methods of study—Hansen's sample of postal routes for estimates of the amount of unemployment in 1936 gained recognition for improved methods; without it the attempt at complete registration of unemployed in the United States at the same time would have been useless.

Mahalanobis commenced in 1932 to measure the yield of jute in Bengal and soon extended his surveys to yields of rice and of other crops. In 1952 all of India came under the national surveys, the scope of which included social studies and studies of family budgets, sickness, births, and deaths. Meanwhile, the efforts of statisticians, mainly in India and England, had brought advances in methodology for estimation of yield per acre by random selection of small plots to be cut and harvested.

A quarterly survey of unemployment in the United States, conducted through interviews in a sample of households within a sample of counties, was begun in 1937. It was soon made monthly, and in 1942 it was remodeled much along its present lines (Hansen et al. 1953, vol. 1, chapter 9).

Sampling was used in the census of the United States in 1940 to extend coverage and to broaden the program of tabulation and publication. Tabulation of the census of India in 1941 was carried out by a 2 per cent sample. Subsequent censuses in various parts of the world have placed even greater dependence on sampling, not only for speed and economy in collection and tabulation but also for improved reliability. The census of France used sampling as a control to determine whether the complete Census of Commerce of 1946 was sufficiently reliable to warrant publication; the decision was negative (Chevry 1949). [For further history, see Stephan 1948. Some special references to history are contained in Deming (1943) 1964, p. 142. See also STATISTICS, article on THE HISTORY OF STATISTICAL METHOD.]

**Misconceptions about sampling.** Sampling, of course, possesses some disadvantages: it does not

furnish detailed information concerning every individual person, account, or firm; furthermore, error of sampling in very small areas and sub-classes may be large. Many doubts about the value of sampling, however, are based on misconceptions. Some of the more common misconceptions will now be listed and their fallacies pointed out.

*It is ridiculous to think that one can determine anything about a population of 180 million people, or even 1 million people, from a sample of a few thousand.* The number of people in the country bears almost no relation to the size of the sample required to reach a prescribed precision. As an analogy (suggested by Tukey), consider a basket of black and white beans. If the beans are really mixed, a cupful would determine pretty accurately the proportion of beans that are black. The cupful would still suffice and would give the same precision for a whole carload of beans, provided the beans in the carload were thoroughly mixed. The problem lies in mixing the beans. As has already been noted, the statistician accomplishes mixing by the use of random numbers.

*Errors of sampling are a hazard because they are ungovernable and unknown. Reliability of a sample is a matter of luck.* Quality and reliability of data are built in through proper design and supervision, with aid from the theory of probability. Uncertainty resulting from small, independent, accidental errors of a canceling nature and variation resulting from the use of sampling are in any case determinable afterward from the results themselves.

*Errors of sampling are the only danger that one has to worry about in data.* Uncertainty in statistical studies may arise from many sources. Sampling is but one source of error. [See below, and see also ERRORS, article on NONSAMPLING ERRORS].

*Electronic data-processing machines, able to store and retrieve information on millions of items with great speed, eliminate any need of sampling.* This is a fanciful hope. The inherent accuracy of original records as edited and coded is the limitation to the accuracy that a machine can turn out. Often, complete records are flagrantly in error or fail to contain the information that is needed. Moreover, machine-time is expensive; sampling reduces cost by reducing machine-time.

*A "complete" study is more reliable than a sample.* Data are the end product of preparation and of a long series of procedures—interviewing, coding, editing, punching, tabulation. Thus, error of sampling is but one source of uncertainty. Poor workmanship and structural limitations in the method of test or in the questionnaire affect a

complete count as much as they do a sample. It is often preferable to use funds for improving the questionnaire and tests rather than for increasing the size of the sample.

**Statistical parts of sampling procedure.** A sampling procedure consists of ten parts. In the following list, *M* will denote those parts that are the responsibility of the expert on the subject matter, and *S* will denote those that are the responsibility of the statistician. (The technical terms used will be defined below.)

(a) Formulation of the problem in statistical terms (probability model) so that data will be meaningful (*M, S*). A problem is generated by the subject matter, not by statistical theory.

(b) Decision on the universe (*M*). The universe follows at once from a careful statement of the problem.

(c) Decision on the frame (*M, S*). Decision on the type and size of sampling units that constitute the frame (*S*).

(d) Procedure for the selection of the sample (*S*).

(e) Procedure for the calculation of estimates of the characteristics desired (averages, totals, proportions, etc.) (*S*).

(f) Procedure for the calculation of standard errors (*S*).

(g) Design of statistical controls, to permit detection of the existence and extent of various non-sampling errors (*S*).

(h) Editing, coding, tabulation (*M, S*).

(i) Evaluation of the statistical reliability of the results (*S*).

(j) Uses of the data (*M*).

### Definitions of terms

The technical terms that have been used above and that will be needed for further discussion will now be defined.

**Universe of study.** The universe consists of all the people, firms, material, conditions, units, etc., that one wishes to study, whether accessible or not. The universe for any study becomes clear from a careful statement of the problem and of the uses intended for the data. Tabulation plans disclose the content of the universe and of the information desired. Examples of universes are (i) the housewives aged 20–29 that will live in the Metropolitan Area of Detroit next year, (ii) all the school children in a defined area, (iii) all the pigs in a country, both in rural areas and in towns.

**Frame.** The frame is a means of access to the universe (Stephan 1936) or to enough of the universe to make a study worthwhile. A frame is composed of sampling units. A sampling unit

commonly used in house-to-house interviewing is a compact group or segment of perhaps five consecutive housing units. A frame is often a map, divided up—either explicitly or tacitly—into labeled areas. In a study concerned with professional men, for example, the frame might be the roster of membership of a professional society, with pages and lines numbered. The sampling unit might be one line on the roster or five consecutive lines.

Without a frame probability sampling encounters numerous operational difficulties and inflated variances (see, for example, the section "Sampling moving populations," below).

In the types of problems to be considered here (with the exception of those treated in the section "Sampling moving populations," below) there will be a frame, and every person, or every housing unit, will belong to one sampling unit, or will have an ascertainable probability of belonging to it. In the sampling of stationary populations, a sampling procedure prescribes rules by which it is possible to give a serial number to any sampling unit, such as a small area. A random number will then select a definite sampling unit from the frame and will lead to investigation of all or a subsample of the material therein that belongs to the universe.

**Selection of persons within a dwelling unit.** Some surveys require information concerning individuals, and in such cases it may be desirable, for various reasons (contagion, fatigue, and so on), to interview only one eligible person in a dwelling unit that lies in a selected segment. In such surveys, the interviewer may make a list of the eligible people in each dwelling unit that falls in the sample and may select therefrom, on the spot, by a scheme based on random numbers, one person to interview. Appropriate weights are applied in tabulation (Deming 1960, p. 240).

**Nominal frame and actual frame.** One must often work with a frame that fails to include certain areas or classes that belong to the universe. A list of areas that contain normal families may not lead to all the consumers of a product, as some consumers may live in quasi-normal quarters, such as trailers and dormitories. Extension of the sampling procedure into these quarters may present problems. Fortunately, the proportion of people in quasi-normal households is usually small (mostly 1 per cent to 3 per cent in American cities), and one may therefore elect to omit them.

A frame may be seriously impaired if it omits too much of certain important classes that by definition belong to the nominal frame. It is substantive judgment, aided by calculation, that must decide whether a proposed frame is satisfactory.

*Sampling from an incomplete frame.* Almost every frame is in some respects out of date at the time of use. It is often possible, however, to use an obsolete or incomplete frame in a way that will erase the defects in the areas that fall into the sample. One may, for example, construct rules by which to select large sampling units from an incomplete frame and then to amend those units, by local inquiry, in order to bring them up to date. Selection of small areas within the larger area, with the appropriate probability, will maintain the prescribed over-all probability of selection.

*Sampling for rare characteristics.* One sometimes wishes to study a rare class of people when there is no reliable list of that class. One way to accomplish this is to carry out a cheap, rapid test in order to separate a sample of households into two groups (strata)—one group almost free of the rare characteristic, the other heavily populated with it—and then to investigate a sample drawn from each group. Optimum sampling fractions and weights for consolidation may be calculated by the theory of stratified sampling (discussed below; see also Kish in Symposium . . ., 1965).

*Equal complete coverage of a frame.* The equal complete coverage of a frame is by definition the result that would be obtained from an investigation of all sampling units in a given frame, carried out by the same field workers or inspectors, using the same definitions and procedures, and exercising the same care as they exercised on the sample, and at about the same period of time. The adjective "equal" signifies that the same methods must be used for the equal complete coverage as for the sample.

*Some operational definitions. Sampling error.* Suppose that for a given frame, sampling units bear the serial numbers 1, 2, 3, and on to  $N$ . However it be carried out, and whatever be the rules for coding and for adjustment for nonresponse, a complete coverage of the  $N$  sampling units of the frame would yield the numerical values

$$a_1, a_2, a_3, \dots, a_N \text{ for } x, \\ b_1, b_2, b_3, \dots, b_N \text{ for } y.$$

In a survey of unemployment, for example, the  $x$ -characteristic of a person might be the property of being unemployed and his  $y$ -characteristic the property of belonging to the labor force. Then  $a_1$ , the  $x$ -population of sampling unit No. 1 (which might consist of five successive households), would be the count of people that have the  $x$ -characteristic in that sampling unit. That is,  $a_1$  would be the count of unemployed persons in the five households. Similarly,  $b_1$ , the  $y$ -population, would be the count of people in the labor force in those same

households. Then  $a_1/b_1$  would be the proportion unemployed in the sampling unit of five households.

Again,  $x$  might refer to expenditure for bread and  $y$  to expenditure for all food. Then  $a_1/b_1$  would be the proportion of money that goes for bread in sampling unit No. 1, expenditure for all food being the base.

Here, the people with the  $x$ -characteristic form a subclass of those with the  $y$ -characteristic, but this may not be so in other surveys. Thus, the  $x$ -characteristic and the  $y$ -characteristic might form a dichotomy, such as passed and rejected or male and female. One often deals with multiple characteristics, but two will suffice here.

Denote the sum of the  $x$ -values and of the  $y$ -values in the  $N$  sampling units by

$$A = a_1 + a_2 + a_3 + \dots + a_N = Na = x\text{-total}, \\ B = b_1 + b_2 + b_3 + \dots + b_N = Nb = y\text{-total},$$

which makes  $a$  and  $b$  the average  $x$ -value and the average  $y$ -value per sampling unit in the frame, as in Table 1. For example,  $A$  might be the total number unemployed in the whole frame and  $B$  the total number of people in the labor force. Then  $\phi = A/B$  would be the proportion of people in the labor force that are unemployed.

An operational definition of the sampling process and of the consequent error of sampling is contained in the following experiment.

(a) Take for the frame  $N$  cards, numbered serially 1 to  $N$ . Card  $i$  shows  $a_i$  and  $b_i$  for the values of the  $x$ -characteristic and  $y$ -characteristic.

(b) Draw a sample of  $n$  cards, following the specified sampling procedure (which will invariably require selection by random numbers).

Table 1 illustrates the notation for the frame and for the results of a sample. The serial numbers on the cards in the sample are not their serial numbers in the frame but denote instead the ordinal number as drawn by random numbers. Sample card No. 1 could be any card from 1 to  $N$  in the frame. In general, another sample would be composed of different cards, as the drawings are random.

(c) Form estimates by the formulas specified in the sampling plan. For illustration, one may form, from the sample, estimators like

$$(1) \quad \bar{x} = \frac{1}{n} \sum_{i=1}^n x_i,$$

$$(2) \quad \bar{y} = \frac{1}{n} \sum_{i=1}^n y_i,$$

$$(3) \quad X = N\bar{x},$$

$$(4) \quad Y = N\bar{y},$$

$$(5) \quad f = \bar{x}/\bar{y}.$$

Table 1 — Some notation for frame and sample

FRAME			SAMPLE		
Serial number of sampling unit	x-value	y-value	Serial number in order drawn in sample	x-value	y-value
1	$a_1$	$b_1$	1	$x_1$	$y_1$
2	$a_2$	$b_2$	2	$x_2$	$y_2$
⋮	⋮	⋮	⋮	⋮	⋮
$N$	$a_N$	$b_N$	$n$	$x_n$	$y_n$
Total	$A$	$B$	$\bar{x}$	$\bar{y}$	
Average per sampling unit	$a = A/N$	$b = B/N$	$\bar{x} = x/n$	$\bar{y} = y/n$	
Variance*	$\sigma_a^2 = \frac{1}{N} \sum_{i=1}^N (a_i - a)^2$	$\sigma_b^2 = \frac{1}{N} \sum_{i=1}^N (b_i - b)^2$	$s_x^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2$	$s_y^2 = \frac{1}{n} \sum_{i=1}^n (y_i - \bar{y})^2$	
Standard deviation	$\sigma_a$	$\sigma_b$	$s_x$	$s_y$	

\* Some authors define variances by means of  $N-1$  and  $n-1$  rather than  $N$  and  $n$ .

If (1), (2), (3), (4), and (5) are used as estimators of  $a$ ,  $b$ ,  $A$ ,  $B$ , and  $\phi$ , respectively, and if the results of the complete coverage were known, then one could, for any experiment, compute errors of sampling, such as

$$\begin{aligned} (6) \quad & \Delta\bar{x} = \bar{x} - a, \\ (7) \quad & \Delta\bar{y} = \bar{y} - b, \\ (8) \quad & \Delta f = f - \phi. \end{aligned}$$

It is an exciting fact that a single sample—provided that it is big enough (usually 25, 30, or more sampling units), and provided that it is designed properly and skillfully in view of possible statistical peculiarities of the frame and is carried out in reasonable conformance with the specifications—will make possible an estimate, based on theory to follow later, of the important characteristics of the distribution of sampling variation of all possible samples that could be drawn from the given equal complete coverage and processed by the specified sampling procedure.

**Standard error and mathematical bias.** We continue our conceptual experiment.

(d) Return the sample of  $n$  cards to the frame, and repeat steps (b) and (c) by the same sampling procedure, to form a new sample and new estimates  $\bar{x}$ ,  $\bar{y}$ ,  $f$ . Repeat these steps again and again, 10,000 times or more.

Explicit statements will now be confined to  $\bar{x}$ . The 10,000 experiments give an empirical distribution for  $\bar{x}$ , by which one may count the number of samples for which  $\bar{x}$  lies between, for example, 100 and 109. We visualize an underlying theoretical distribution of  $\bar{x}$ , which the empirical dis-

tribution approaches closer and closer as the number of repetitions increases.

We are typically concerned with relationships between (i) the empirical distribution of  $\bar{x}$  and (ii) the theoretical distribution of  $\bar{x}$ , for the given sampling procedure. Study of these relationships helps in the use of sampling for purposes of making estimates of characteristics of the frame.

Let  $a$  be the characteristic of the complete coverage that the generic symbol  $\bar{x}$  estimates. Then if

$$(9) \quad E\bar{x} = a,$$

the sampling procedure is said to be unbiased. (The symbol  $E$  denotes *expectation*, the mean of the theoretical distribution of  $\bar{x}$ .) But if

$$(10) \quad E\bar{x} = a + C, \quad C \neq 0,$$

the sampling procedure has the mathematical bias  $C$ . In any case, the variance of the distribution of  $\bar{x}$  is

$$(11) \quad \sigma_{\bar{x}}^2 = E(\bar{x} - E\bar{x})^2,$$

and its square root,  $\sigma_{\bar{x}}$ , is the standard error of the sampling procedure for the estimator  $\bar{x}$ . Thus, a sampling procedure has, for any estimator, an expected value, a standard error, and possibly a mathematical bias (see the section "Possible bias in ratio estimators," below).

**Uncertainty from accidental variation.** Under the conditions stated above, the margin of uncertainty in the estimator  $\bar{x}$  that is attributable to sampling and to small, independent, accidental variations, including random error of measurement (Type III in the next section), may be estimated, for a specified probability, as  $t\hat{\sigma}_{\bar{x}}$ , where  $\hat{\sigma}_{\bar{x}}$  is an

estimator of  $\sigma_x$ . The factor  $t$  depends on the probability level selected for the margin of uncertainty (which will in turn depend on the risks involved) and also on the number of degrees of freedom in the estimator  $\hat{\sigma}_x$ . In large samples the distributions of most estimators are nearly normal, except for frames that exhibit very unusual statistical characteristics. The standard deviation,  $\sigma_x$ , then contains nearly all the information regarding the margin of uncertainty of  $\bar{x}$  that is attributable to accidental variation. Presentation of the results of a survey requires careful consideration when there is reason to question the approximate normality of estimators (Fisher 1956, p. 152; Shewhart 1939, p. 106).

**Random selection.** It is never safe to assume, in statistical work, that the sampling units in a frame are already mixed. A frame comes in layers that are different, owing to geographic origin or to order of production. Even blood, for example, has different properties in different parts of the body.

A random variable is the result of a random operation. A system of selection that depends on the use, in a standard manner, of an acceptable table of random numbers is acceptable as a random selection. Methods of selection that depend on physical mixing, shuffling, drawing numbers out of a hat, throwing dice, are not acceptable as random, because they have no predictable behavior. Neither are schemes that merely remove the choice of sampling units from the judgment of the interviewer. Pseudo-random numbers, generated under competent skill, are well suited to certain types of statistical investigation [see RANDOM NUMBERS].

### Types of uncertainty in statistical data

All data, whether obtained by a complete census or by a sample, are subject to various types of uncertainty. One may reduce uncertainties in data by recognizing their existence and taking steps for improvement in future surveys. Sample design is an attempt to strike an economic balance between the different kinds of uncertainty. There is no point, for example, in reducing sampling error far below the level of other uncertainties.

**Three types of uncertainty.** The following discussion will differentiate three main types of uncertainty.

**Type I.** Uncertainty of Type I comprises built-in deficiencies, or structural limitations, of the frame, questionnaire, or method of test.

Any reply to a question, or any record made by an instrument, is only a response to a stimulus. What stimulus to apply is a matter of judgment. Deficiencies in the questionnaire or in the method of test may therefore arise from incomplete under-

standing of the problem or from unsuitable methods of investigation. Structural limitations are independent of the size or kind of sample. They are built in: a recanvass will not discover them, nor will calculation of standard errors or other statistical calculations detect them.

Some illustrations of uncertainty of Type I are the following:

(a) The frame may omit certain important segments of the universe.

(b) The questionnaire or method of test may fail to elicit certain information that is later found to be needed. The questionnaire may contain inept definitions, questions, and sequences. Detailed accounting will give results different from those given by mere inquiry about total expenditure of a family for some commodity; date of birth gives a different age from that given in answer to the simple question, How old are you? There may be differential effects of interviews depending on such variables as sex and race of the interviewer.

(c) Use of telephone or mail may yield results different from those obtained by personal interview.

(d) Judgments of coders or of experts in the subject matter may differ.

(e) The date of the survey has an important effect on some answers.

**Type II.** Uncertainty of Type II includes operational blemishes and blunders—for example:

(f) One must presume the existence of errors of a noncanceling nature (persistent omission of sampling units designated, persistent inclusion of sampling units not designated, persistent favor in recording results).

(g) One must presume the existence of bias from nonresponse.

(h) Information supplied by coders for missing or illegible entries may favor high or low values.

(i) There may be a large error, such as a unique blunder.

**Type III.** Uncertainty of Type III is caused by random variation. Repeated random samples drawn from the same frame will give different results. Besides, there are inherent uncorrelated, nonpersistent, accidental variations of a canceling nature that arise from inherent variability of investigators, supervisors, editors, coders, punchers, and other workers and from random error of measurement.

**Standard error of an estimator.** The standard error of a result includes the combined effects of all kinds of random variation, including differences within and between investigators, supervisors, coders, etc. By proper design, however, it is possible to get separate estimates of some of these differences.

A small standard error of a result signifies

(i) that the variation between repeated samples will be small and (ii) that the result of the sample agrees well with the equal complete coverage of the same frame. It usually tells little about uncertainties of Type II and never anything about uncertainties of Type I.

**Limitations of statistical inference.** Statistical inference (estimates, standard errors, statistical tests) refers only to the frame that was sampled and investigated. No statistical calculation can, by itself, detect or measure nonsampling errors, although side experiments or surveys may be helpful. No statistical calculation can detect defects in the frame. No statistical calculation can bridge the gap between the frame covered and the universe. This is as true of probability sampling as it is of judgment sampling, and it is true for a complete census of the frame as well.

**Comparison of surveys.** Substantial differences in results may come from what appear to be inconsequential differences in questionnaires or in methods of hiring, training, and supervision of interviewers and coders or in dates of interviewing. The sampling error in a sample is thus not established by comparison against a complete census unless the complete census is the equal complete coverage for the sample.

**Recalls on people not at home.** Many characteristics of people that are not at home at first call, or that are reluctant to respond, may be very different from the average. What is needed is response from everyone selected, including those that are hard to get. To increase the initial size of the sample is no solution. Calculations that cover a wide variety of circumstances show that the amount of information per dollar expended on a survey increases with the number of recalls, the only practicable limit being the time for the completion of the survey. Good sample design therefore specifies that four to six well-timed recalls be made or specifies that recalls continue until the level of response reaches a prescribed proportion. Special procedures, such as intensive subsampling of those not at home on the first or second call, have been proposed (see Leven 1932; Hansen & Hurwitz 1946; Deming 1960).

**Surveys by post.** One can often effect important economies by starting with a mail survey of a fairly large sample properly drawn from a given frame, then finishing with a final determined effort in the form of personal interviews on all or a fraction (one in two or one in three) of the people that failed to reply (Leven 1932). Mail surveys require a frame, in the form of a list of names with reasonably accurate addresses, and provision for keeping records of mailings and of returns.

They are therefore especially adaptable to surveys of members of a professional society, subscribers to a journal, or subscribers to a service. [For further discussion of mail surveys, see ERRORS, article on NONSAMPLING ERRORS.]

### Simple designs for enumerative purposes

The aim in an *enumerative* study is to count the number of people in an area that have certain characteristics or to estimate a quantity, perhaps their annual income, regardless of how they acquired these characteristics. The aim in an *analytic* study is to detect differences between classes or to measure the effects of different treatments.

For illustration consider a study of schizophrenics. One enumerative aim might be to estimate the number of children born to schizophrenic parents before onset of the disease or before the first admission of one of the parents to a hospital for mental diseases. Further aims of the same study might be analytic, such as to discover differences in fertility or in duration of hospitalization caused by different treatments, differences between communities, or differences between time periods.

The finite multiplier typified by  $1/n - 1/N$  (to be seen later) appears in estimators for enumerative purposes. It has no place in estimators for analytic purposes.

Optimum allocation of effort for an enumerative aim may not be optimum for an analytic aim. Moreover, what is optimum for one enumerative characteristic may not be optimum for another. Hence, it will usually be necessary to compromise between competitive aims.

Enumerative aims will occupy most of the remaining space in this article.

The theory presented in this section is for the design commonly called *simple random sampling*. This is often a practicable design, and the theory forms a base for more complex designs.

**A simple procedure of selection and some simple estimators.** Definitions of "frame," "sample," and other terms were introduced above. In addition, it will be convenient to define the *coefficient of variation*. For the  $x$ -population and  $y$ -population of the frame, the coefficients of variation are defined as

$$(12) \quad C_x = \frac{\sigma_x}{\bar{x}}, \quad C_y = \frac{\sigma_y}{\bar{y}}, \quad a > 0, b > 0.$$

In like manner, the symbol  $C_x$  denotes the coefficient of variation of the empirical or theoretical distribution of the random variable  $x$ . The square,  $C_x^2$ , of the coefficient of variation  $C_x$  is called the *rel-variance* of  $x$ . The coefficient of variation is especially useful for characteristics (such as height)

that are positive. It is often helpful to remember, for example, that  $C_x = C_y = C_z$  because  $x$ ,  $\bar{x}$ , and  $X$  are constant multiples of each other.

The procedure of selection specified earlier gives every member of the frame the same probability of selection as every other member, wherefore

$$(13) \quad \begin{aligned} E\bar{x} &= a, \\ E\bar{y} &= b. \end{aligned}$$

That is,  $\bar{x}$  and  $\bar{y}$  are unbiased estimators of  $a$  and  $b$ , respectively. Moreover,

$$(14) \quad \begin{aligned} X &= N\bar{x}, \\ Y &= N\bar{y} \end{aligned}$$

are unbiased estimators of  $A$  and  $B$ .

Often, a ratio such as

$$(15) \quad \phi = \frac{A}{B} = \frac{a}{b}$$

is of special interest. The sample gives

$$(16) \quad f = \frac{X}{Y} = \frac{x}{y} = \frac{\bar{x}}{\bar{y}}$$

as an estimator of  $\phi$ . If the total  $y$ -population,  $B$ , is known from another source, such as a census,  $A$  may be estimated by the formula

$$(17) \quad X' = Bf.$$

This estimator  $X'$  is called a *ratio estimator*. It will be more precise than the estimator  $X = N\bar{x}$  in (14) if the correlation between  $x_i$  and  $y_i$  is high. Other estimators will be discussed later (for example, regression estimators). Theory provides a basis for the choice of estimator.

**Possible bias in ratio estimators.** Necessary and sufficient conditions for there to be no bias in  $f$  as an estimator of  $\phi$  are that  $Ey \neq 0$  and that  $x_i/y_i$  and  $y_i$  be uncorrelated—that is, that  $E[(x/y)y] = E(x/y)Ey$ . In practice, if bias exists at all, it is usually negligible when the sample contains more than three or four sampling units.

**Sampling with and without replacement.** Usually, in the sampling of finite populations, one permits a sampling unit to come into the sample only once. In statistical language, this is sampling *without replacement*. Tests of physical materials are sometimes destructive, and a second test would be impossible. To draw without replacement, one simply disregards a random number that appears a second time (or uses tables of so-called random permutations).

There are circumstances, however, in which one accepts the random numbers as they come and permits a sampling unit to come into the sample more than once. This is sampling *with replacement*.

Hereafter, most equations will be written for

sampling without replacement. It is a simple matter to drop the fraction  $1/N$  from any formula to get the corresponding formula for sampling with replacement. Actually, in practice, samples are usually such a small part of the frame that the fraction  $1/N$  is ignored, even though the sampling be done without replacement.

**Variances.** The variances of the estimator  $\bar{x}$  derived from the sampling procedure described earlier are

$$(18) \quad \left\{ \begin{array}{ll} \text{without} & \sigma_{\bar{x}}^2 = \frac{N-n}{N-1} \frac{\sigma^2}{n} \\ \text{replacement} & \approx \left( \frac{1}{n} - \frac{1}{N} \right) \sigma^2, \\ \\ \text{with} & \sigma_{\bar{x}}^2 = \frac{\sigma^2}{n}. \\ \text{replacement} & \end{array} \right.$$

(The sign  $\approx$  indicates an approximation that is sufficiently close in most practice.)

Similar expressions hold for  $\bar{y}$ . For the ratio  $f = \bar{x}/\bar{y}$ , the approximation

$$(19) \quad C_f^2 \approx \left( \frac{1}{n} - \frac{1}{N} \right) (C_x^2 + C_y^2 - 2abC_{xy})$$

is useful if  $n$  be not too small. Here

$$(20) \quad C_{xy} = \frac{1}{Nab} \sum (a_i - a)(b_i - b)$$

is the rel-covariance of the  $x$ -population and  $y$ -population per sampling unit in the frame.

When the ratio estimator of the total  $x$ -population is derived as in eq. (17), eq. (19) gives the same approximation for  $C_{f'}^2$ .

**Estimate of aggregate characteristic—number of units in class unknown.** It often happens in practice that one wishes to estimate the aggregate value of some characteristic of a subclass of a group when the total number of units in the subclass is unknown. For example, one might wish to estimate the aggregate income of women aged 15 or over that live in a certain district, are gainfully employed, and have at least one child under 12 years old at home (this specification defines the universe). The number of women that meet this specification is not known. An estimate of the average income per woman of this specification, prepared from a sample, suffers very little from this gap in available knowledge, but an estimate of the total income of all such women is not so fortunate.

As an illustration, suppose that the frame is a serialized list of  $N$  women aged 15 or over and that the sample is a simple random sample of  $n$  of these women, drawn with replacement by reading out  $n$  random numbers between 1 and  $N$ . Informa-

tion on the  $n$  women is collected, and it is noted which ones belong to the specified subclass—that is, which ones live in a certain district, are gainfully employed, and have at least one child under 12 years old at home. Suppose that this number is  $n_s$  and that the average income of the  $n_s$  women is  $\bar{x}_s$ . Of course,  $n_s$  is a random variable with a binomial distribution.

What is the rel-variance of  $\bar{x}_s$ ? Let  $C_s^2$  be the rel-variance between incomes of the women in the frame that belong to the subclass. It is a fact that the conditional rel-variance of  $\bar{x}_s$ , for samples of size  $n_s$  of the specified subclass, will be  $C_s^2/n_s$ , just as if the women of this subclass had been set off beforehand into a separate stratum and a sample of size  $n_s$  had been drawn from it.

The conditional expected value of  $\bar{x}_s$  over all samples of fixed size  $n_s$  in the subclass has moreover the convenient property of being the average income of all the women in the frame that belong to this subclass. It is for this reason that the conditional rel-variance of  $\bar{x}_s$  is useful for assessing the precision of a sample at hand. For purposes of design, one uses the rel-variance of  $\bar{x}_s$  over all samples of size  $n$ , which is  $C_s^2 E(1/n_s)$ , or very nearly  $C_s^2[1 + Q/nP]/nP$ , where  $P$  is the proportion of all women 15 or over that meet the specification of the subclass, and  $P + Q = 1$ .

In contrast, any estimator,  $X_s$ , of the aggregate income of all the women in the specified subclass will not have such convenient properties as  $\bar{x}_s$ . The conditional expectation of  $X_s$ , for samples of size  $n_s$ , is not equal to the aggregate income of all the women in the frame that belong to the subclass. The conditional rel-variance of  $X_s$  for a sample of size  $n_s$  at hand, although equal to the conditional rel-variance of  $\bar{x}_s$ , therefore requires careful interpretation. Instead of attempting to interpret the conditional rel-variance of  $X_s$ , one may elect to deal with the variance of  $X_s$  in all possible samples of size  $n$ . Thus, if  $X_s$  is set equal to  $(N/n)n_s\bar{x}_s$  (here  $N/n$  is used as an expansion factor equal to the reciprocal of the probability of selection), it is a fact that the rel-variance of  $X_s$  over all samples of size  $n$  will be  $(C_s^2 + Q)/nP$  (see Deming 1960, p. 129).

The problem with  $X_s$  arises from the assumption that  $N_s$ , the number of women in the frame that meet the specification of the subclass, is unknown. If  $N_s$  were known, one could form the estimator  $X_s = N_s\bar{x}_s$ , which would have all the desirable properties of  $\bar{x}_s$ .

One way to reduce the variance of the total income,  $X_s$ , of the specified class is (1) to select from the frame a large preliminary sample, (2) by

an inexpensive investigation to classify the units of the preliminary sample into two classes, those that belong to the specified class and those that do not, (3) to investigate a sample of the units that fell into the specified class, to acquire information on income. The preliminary sample provides an estimate of  $N_s$ , and the final sample provides an estimate of  $\bar{x}_s$ . The product gives the estimate  $X_s = N_s\bar{x}_s$  for the total income in the specified class. (For the variance of  $X_s$  and for optimum sizes of samples, see Hansen, Hurwitz, & Madow, 1953, vol. 1, pp. 65 and 259.)

If, further,  $N$  were not known and only the probability,  $\pi$ , of selection, to be applied to every sampling unit in the frame, were known, both  $n$  and  $n_s$  will be random variables, and there will be a further inflation of the rel-variance of any estimator of the aggregate income of all the women in the specified subclass. Thus, if  $X_s$  be set equal to  $n_s\bar{x}_s/\pi$  for such an estimator, then the unconditional rel-variance of  $X_s$  will be  $(C_s^2 + 1)/nP$ . The conditional rel-variance of  $\bar{x}_s$ , however, is still  $C_s^2/n_s$ .

It may be noted that for a small subclass there is little difference between  $C_s^2 + Q$  and  $C_s^2 + 1$ .

Examples are common. Thus, one might read out a two-digit random number for each line of a register, following the rule that the item listed on a line will be drawn into the sample if the random number is 01. If counts from outside sources are not at hand or are not used, then the rel-variance of an estimator,  $X_s$ , of the total number or total value of any subclass of items on the register contains the factor  $C_s^2 + 1$ .

*Use of thinning digits.* Reduction of the probability of selection of units of specified characteristics (such as items of low value) through the use of thinning digits may produce either the factor  $C_s^2 + Q$  or the factor  $C_s^2 + 1$  in the rel-variance of an estimator of an aggregate, depending on the mode of selecting the units.

*Estimates of variances.* Estimates of variances are supplied by the sample itself, under proper conditions, as was discussed above. Some of the more important estimators follow, denoted by a circumflex ( $\hat{\phantom{x}}$ ). For the variance of  $\bar{x}$ ,

$$(21) \quad \hat{\sigma}_{\bar{x}}^2 = \left(\frac{1}{n} - \frac{1}{N}\right) \frac{1}{n-1} \sum (x_i - \bar{x})^2,$$

with a similar expression for  $\hat{\sigma}_{\bar{y}}^2$ . For the covariance,

$$(22) \quad \hat{\sigma}_{\bar{x}\bar{y}} = \left(\frac{1}{n} - \frac{1}{N}\right) \frac{1}{n-1} \sum (x_i - \bar{x})(y_i - \bar{y}).$$

Eqs. (21) and (22), with  $N$  infinite, were developed by Gauss (1823). These estimators are un-

biased;  $\sqrt{\hat{\sigma}_x^2}$  is a slightly biased estimator of  $\sigma_x$ , but the bias is negligible for  $n$  moderate or large.

Under almost all conditions met in practice, one may set

$$(23) \quad t = \frac{\bar{x} - E\bar{x}}{\hat{\sigma}_x}$$

and compare this quantity with tabulated values of  $t$  to find the margin of uncertainty in  $\bar{x}$  for any specified probability. Such calculations give excellent approximations unless the distribution of sampling units in the frame is highly skewed. Extreme skewness may often be avoided by stratification (discussed below).

A useful approximate estimator for the rel-variance of  $f = X/Y = \bar{x}/\bar{y}$  is

$$(24) \quad \hat{C}_f^2 \approx \left(\frac{1}{n} - \frac{1}{N}\right) \frac{1}{(\bar{n} - 1)\bar{x}^2} \sum (x_i - f y_i)^2.$$

This formula is derived by combination of eqs. (19), (21), and (22). In accordance with a previous remark, one may take  $\hat{C}_{X'} = \hat{C}_f$ , where  $X'$  is the ratio estimator of  $A$  as given by (17).

**Size of frame usually not important.** Because of the way in which  $N$  enters the variances, the size of the frame has little influence on the size of sample required for a prescribed precision, unless the sample is 20 per cent or more of the total frame. For instance, the sample required to reach a specified precision would be the same for the continental United States as for the Boston Metropolitan Area, on the assumption that the underlying variances encountered are about the same for the entire United States as for Boston.

**Special form for attributes (0,1 variate).** In many studies a sampling unit gives only one of two possible observations, such as *yes* or *no*, *male* or *female*, *heads* or *tails*. The above equations then assume a simple form.

If each person in a frame is a sampling unit, and if  $a_i = 1$  for *yes*,  $a_i = 0$  for *no*, then the total  $x$ -population,  $A$ , in the frame is the total number of *yes* observations that would be recorded in the equal complete coverage, and  $a$  is the proportion *yes*, commonly denoted by  $p$ . The variance between the  $a_i$  in the frame is

$$(25) \quad \sigma_a^2 = pq,$$

where  $p + q = 1$ .

The random variate,  $x_i$ , will take the value 0 or 1;

$$(26) \quad x = \sum x_i$$

will be the number of *yes* observations in the sample, and

$$(27) \quad \hat{p} = x/n$$

will be the proportion *yes* in the sample. Replacement of  $\bar{x}$  by  $\hat{p}$  in previous equations shows that  $\hat{p}$  is an unbiased estimator of the proportion *yes* in the frame and that

$$(28) \quad \sigma_{\hat{p}}^2 = \left(\frac{1}{n} - \frac{1}{N}\right) pq.$$

It is important to note that this variance is valid only if each sampling unit produces the value 0 or 1. It is not valid, for instance, for a sample of segments of area if there is more than one person per segment, or if the segments are clustered (as discussed below).

For an estimate of the variance of  $\hat{p}$  (provided the sampling procedure meets the conditions stated) one may use

$$(29) \quad \hat{\sigma}_{\hat{p}}^2 = \left(\frac{1}{n} - \frac{1}{N}\right) \hat{p}\hat{q},$$

where  $\hat{p} + \hat{q} = 1$ .

**How good is an estimator of a variance?** The variance of the estimator  $\hat{\sigma}_x^2$  in eq. (21) depends on the standardized fourth moment,  $\beta_2$ , of the frame and on the number of degrees of freedom for the estimator. Thus, if one defines

$$(30) \quad \beta_2 = \frac{1}{N} \sum \left( \frac{a_i - a}{\sigma} \right)^4,$$

then the rel-variance of the estimator  $\hat{\sigma}_x^2$  of eq. (21) will be  $(\beta_2 - 1)/n$ , which diminishes with  $n$ .

**Systematic selection.** A simple and popular way to spread the sample over the frame is to select every  $Z$ th unit, with a random start between 1 and  $Z$ , where  $Z = N/n$ . This is called systematic sampling with a single random start, and it is one form of patterned sampling. In certain kinds of materials, specifically those in which nearby sampling units are, on the average, more similar than units separated by a longer interval, systematic sampling will be slightly more efficient than stratified random sampling (Cochran 1946).

A disadvantage of systematic sampling with a single random start is that there is no strictly valid way to make a statistical estimate of the standard error of a result so obtained. This is because the single start is equivalent to the selection of only one sampling unit from the  $Z$  possible sampling units that could be formed. One may nevertheless, under proper conditions, get a useful approximation to the rel-variance by using the sum of squares of successive pairs. Eq. (21) with  $n = 2$  and  $N = Z$  gives the estimator

$$(31) \quad \hat{C}_x^2 = \left(1 - \frac{2}{Z}\right) \frac{\sum (x_{i1} - x_{i2})^2}{[\sum (x_{i1} + x_{i2})]^2},$$

where the summation runs over all pairs.

Hidden and unsuspected periodicities often turn up, and in such cases the above formula may give a severe underestimate or overestimate of the variance. For example, every  $n$ th household might be nearly in phase with the natural periodicity of income, rent, size of family, and other characteristics associated with corners and with the configuration of dwelling units within areas and within apartment houses. Systematic sampling of physical elements or of time intervals can lead to disaster.

A statistician will therefore justify a single random start and use of eq. (31) only if he has had long experience with a body of material.

Instead of a single random start between 1 and  $N/n$ , one may take two random starts between 1 and  $2N/n$  and every  $(2N/n)$ th sampling unit thereafter. Extension to multiple random starts is obvious. Two or more random starts give a valid estimate of the variance. Fresh random starts every six or eight zones will usually reap any possible advantage of systematic sampling and will avoid uncertainty in estimation of the variance.

**Efficiency of design.** The relative efficiency of two sampling procedures, I and II, that give normally distributed estimators of some characteristic is by definition the ratio of the inverses of the variances of these estimators for the same size,  $n$ , of sample. In symbols ( $E$  denotes efficiency),

$$(32) \quad \frac{E_I}{E_{II}} = \frac{\sigma_{II}^2}{\sigma_I^2}, \quad n_I = n_{II}.$$

This concept of efficiency is due to Fisher (1922).

Comparison of costs is usually more important than comparison of numbers of cases. Let the costs be  $c_I$  and  $c_{II}$  for equal variances. Then

$$(33) \quad \frac{E_I}{E_{II}} = \frac{c_{II}}{c_I}, \quad \sigma_I = \sigma_{II}.$$

Comparison of efficiencies of estimators whose distributions depart appreciably from normality require special consideration.

**Sampling moving populations.** A possible procedure in sampling moving populations is to count and tag all the people visible from a number of enumerators' posts through a period of a day or a week (the first round) and then to repeat the count from the same or different posts some time later (the second round). The  $n_1$  people counted and tagged in the first round constitute a mobile frame for the second round. If the number of people counted in the first round is  $n_1$ , and if the number counted in the second round is  $n_2$ , with an intersection of  $n_{12}$  for people counted in both rounds, then an estimator of the total number of mobile inhabitants in the whole area is  $\hat{N} = n_1 n_2 / n_{12}$  (Yates 1949, p. 43; Deming & Keyfitz 1967).

## More complex designs

**Considerations of cost—clustering.** The total cost of a survey includes cost of preparing the frames and cost of travel to the units selected. In some surveys it may be possible to get more information per unit cost by enlarging the sampling unit, a procedure commonly called *clustering*. One may, for example, define a sampling unit as comprising all the dwellings in a compact segment of area. Further, one may, with experience and care, subsample dwelling units from a selected cluster or select one member of a family where two or more members qualify for the universe. Again, in a national survey, one may restrict the sample to a certain number of counties that will come into the sample by a random process. Or, in a survey of a city, one may restrict the sample to a random selection of blocks.

Any such plan reduces the interviewer's expenses for travel and reduces the cost of preparing the frame. However, restriction of the sample usually also increases variances, unless the total number of households in the sample be increased as compensation. It should be remembered, though, that the actual precision obtained by the use of cluster sampling may be nearly as good as that obtained by an unrestricted random selection of the same number of dwelling units with no clustering.

Theory indicates the optimum balance between enlargement of the sampling unit and the number of sampling units to include in the sample. Obviously, the theory is more complex than that discussed in the last section. Stratification, ratio estimators, and regression estimators are additional techniques that, under certain conditions, yield further increases in efficiency (see below).

**An example.** The following illustration refers to a sample of a city: (i) Suppose that it has been determined in advance that for the main purposes of a survey the optimum size of areal unit is a compact group of five dwelling units, called a segment. (ii) A sampling unit within the city will consist of  $\bar{n}$  segments from a larger number of segments contained in a block. The  $\bar{n}$  segments of a sampling unit (if  $\bar{n} > 1$ ) should be scattered over the block. A good way to effect this scatter is by a systematic selection. (iii) The  $m$  sampling units in the city will be selected by random numbers. For simplicity, assume that all blocks in the city contain an equal number,  $\bar{N}$ , of segments. Suppose that there are

$M$  blocks in the whole city,

$\bar{N}$  segments in a block,

$N = M\bar{N}$  segments in the whole city,

$\bar{n}$  segments in a sampling unit,  
 $\bar{N}/\bar{n}$  sampling units in a block,  
 $M\bar{N}/\bar{n}$  or  $N/\bar{n}$  sampling units in the whole city,  
 $m$  sampling units in the sample.

Then if

$$(34) \quad \bar{x} = x/m\bar{n},$$

one may take

$$(35) \quad X = N\bar{x}$$

for an estimator of the  $x$ -population in the whole city. For this estimator,

$$(36) \quad C_x = C_{\bar{x}},$$

and

$$(37) \quad \text{var } \bar{x} = \frac{N - m\bar{n}}{N - \bar{n}} \left( \frac{\sigma_b^2}{m} + \frac{\bar{N} - \bar{n}}{\bar{N} - 1} \frac{\sigma_w^2}{m\bar{n}} \right).$$

If  $m$  is small compared with  $M$ ,

$$(38) \quad \text{var } \bar{x} \cong \frac{\sigma_b^2}{m} + \frac{\bar{N} - \bar{n}}{\bar{N} - 1} \frac{\sigma_w^2}{m\bar{n}}.$$

If, also,  $\bar{n}$  is small compared with  $\bar{N}$ ,

$$(39) \quad \text{var } \bar{x} \cong \frac{\sigma_b^2}{m} + \frac{\sigma_w^2}{m\bar{n}}.$$

Here  $\sigma_b^2$  is the variance between blocks of the mean  $x$ -population per sampling unit, and  $\sigma_w^2$  is the average variance between sampling units within blocks.

**Important principle in size of secondary unit.** Suppose that the cost of adding one more block to the sample is  $c_1$  (cost of maps, preparation, delineation of segments, travel) and that the cost of an interview in an additional sampling unit is  $c_2$ . Then the total cost of the survey will be

$$(40) \quad K = mc_1 + m\bar{n}c_2.$$

In eq. (37)  $\text{var } \bar{x}$  will be at its minimum for a fixed cost  $K$  if

$$(41) \quad \bar{n} = \frac{\sigma_w}{\sigma_b} \sqrt{\frac{c_1}{c_2}}, \quad \text{optimum } \bar{n}.$$

This equation was derived by both L. H. C. Tippett and Shewhart, independently, in 1931.

Note that  $m$  does not appear in this equation. That is, the optimum value of  $\bar{n}$  on the basis of the cost function (40) is independent of  $m$ , the number of sampling units in the sample (and very nearly independent of the number of blocks in the sample).

The optimum  $m$  is found by substituting the optimum  $\bar{n}$  from eq. (41) into eq. (40) and solving for  $m$ . Of course, it is necessary to assume values for  $\sigma_w/\sigma_b$  and for  $\sqrt{c_1/c_2}$  to do this. (Be-

cause each sampling unit will usually fall in a different block,  $m$  will usually be exactly or nearly as large as the number of blocks in the sample.) Usual numerical values of  $\sigma_w/\sigma_b$  and of  $c_1/c_2$  lead to small values of  $\bar{n}$  and to large values of  $m$ . Efficient design therefore usually requires a small sample from a block and dispersion of the sample into a large number of blocks.

Extension of this theory to a national sample, and to stratified designs and ratio estimators, leads to the same principle.

Variation in size of segment will increase  $\text{var } \bar{x}$  by the factor  $1 + C_n^2/\bar{n}$ , where  $C_n^2$  is the rel-variance of the distribution of the number of dwelling units per segment. A similar factor,  $1 + C_{N_i}^2/m$ , measures the increase in  $\text{var } \bar{x}$  from variation in the number of segments per block.

**Replicated designs for ease in estimation of variance.** Replication of a sample in two or more interpenetrating networks of samples will provide a basis for rapid calculation of a valid estimate of the standard error of any result, regardless of the complexity of the procedure of selection and of the formulas for the formation of estimates [Mahalanobis 1944; Deming 1950; 1960; see also INDEX NUMBERS, article on SAMPLING].

### Stratified sampling

The primary aim of stratified sampling is to increase the amount of information per unit of cost. A further aim may be to obtain adequate information about certain strata of special interest.

One way to carry out stratification is to rearrange the sampling units in the frame so as to separate them into classes, or strata, and then to draw sampling units from each class. The goal should be to make each stratum as homogeneous as possible, within limitations of time and cost. Stratification is equivalent to blocking in the design of an experiment. It is often a good plan (i) to draw a preliminary sample from the frame without stratification; (ii) to classify into strata the units in the preliminary sample, and (iii) to draw, for the final sample, a prescribed number of sampling units from each stratum so formed. Step (i) will sometimes require an inexpensive investigation or test of every sampling unit in the preliminary sample to determine which stratum it belongs to.

Stratification is one way to make use of existing information concerning the frame other than the information obtained from investigating the sampling units in the final sample itself. Other ways to use existing information are through ratio estimators and regression estimators (see below).

In practice a frame is to some extent naturally

Table 2 — Notation and definitions for the frame ( $M = 2$  strata)

STRATUM	NUMBER OF SAMPLING UNITS		STRATUM'S PROPORTION OF SAMPLING UNITS IN THE FRAME	POPULATION		BETWEEN THE POPULATIONS OF THE SAMPLING UNITS WITHIN THE STRATUM	
	In the frame	In the sample		Average per sampling unit in the stratum	Total in the stratum	Standard deviation	Variance
1	$N_1$	$n_1$	$P_1 = \frac{N_1}{N}$	$a_1$	$A_1 = N_1 a_1$	$\sigma_1$	$\sigma_1^2$
2	$N_2$	$n_2$	$P_2 = \frac{N_2}{N}$	$a_2$	$A_2 = N_2 a_2$	$\sigma_2$	$\sigma_2^2$
Total for the frame	$N$	$n$	1	—	$A$	—	—
Unweighted average per stratum	$\bar{N} = \frac{N}{M}$	$\bar{n} = \frac{n}{M}$	$\frac{1}{M}$	—	$\bar{A} = \frac{A}{M}$	—	—
Weighted average per sampling unit	—	—	—	$a = \frac{A}{N}$	—	$\sigma_w$	$\sigma_w^2$

Source: Deming 1960, p. 286.

stratified to begin with. Thus, areas in geographic order usually are already pretty well stratified in respect to income, occupation, density of population, tastes of the consumer, and other characteristics. No frame arrives thoroughly mixed, and any plan of sampling should be applied by zones, so as to capture the natural stratification. Theory serves as a guide to determine whether further stratification would be profitable.

Plans of stratification for enumerative studies. Several plans of stratified sampling for enumerative studies will now be described.

The notation and definitions to be used in this discussion are given in tables 2 and 3. (Note that  $\bar{N}$  and  $\bar{n}$  are defined differently here than they were earlier.) These tables are presented in terms of two strata ( $M = 2$ ), but extension to a greater number of strata follows obviously. The following additional definitions are needed:

$$(42) \quad \sigma_R^2 = Q_1 \sigma_1^2 + Q_2 \sigma_2^2 + Q_3 \sigma_3^2,$$

the average reverse variance between sampling units within strata, and

$$(43) \quad \bar{\sigma}_R = Q_1 \sigma_1 + Q_2 \sigma_2 + Q_3 \sigma_3,$$

the average reverse standard deviation between sampling units within strata, where  $Q_1 + P_1 = 1$ .

*Plan A (no stratification):* The scheme of sampling described above will be designated plan A. It is needed here for comparison, and also because it constitutes the basis for selection from any stratum.

Note that in plan A, as in plans B, D, F, and H, below, all the sampling units in the frame have equal probability of selection, namely  $n/N$ , wherefore  $E\bar{x} = a$  and  $EX = A$ .

*P<sub>1</sub> known—whole frame classified.* Two sampling plans for which the proportions in each stratum are known (or ascertainable) and the the whole frame is classified will now be described.

*Plan B (proportionate sampling):* Decide with the help of eq. (47) the size,  $n$ , of the sample required. Compute next

$$(44) \quad n_i = nN_i/N = nP_i.$$

Draw by random numbers, as in plan A, a sample of size  $n_i$  from stratum  $i$ . Investigate every member of the sample, and calculate

$$(45) \quad X_1 = N_1 x_1/n_1, \quad X_2 = N_2 x_2/n_2, \quad \text{etc.}$$

Table 3 — Notation and definitions for the sample

Stratum	Population in the sample	Mean population per sampling unit	Estimated total population	Variance of this estimator*
1	$x_1$ x-population in stratum 1	$\bar{x}_1 = \frac{x_1}{n_1}$	$X_1 = N_1 \frac{x_1}{n_1}$	$\text{var } X_1$
2	$x_2$ x-population in stratum 2	$\bar{x}_2 = \frac{x_2}{n_2}$	$X_2 = N_2 \frac{x_2}{n_2}$	$\text{var } X_2$
Sum	$x$	—	$X$	$\text{var } X$

\* The variances are additive only if the  $N_i$  (or  $P_i$ ) are known and used in the estimator  $X$ .

(For simplicity, most formulas will henceforth be written for two strata, in conformance with tables 2 and 3. Extension to more strata is obvious.) Here,  $n_i/N_i = n/N$ , wherefore

$$\begin{aligned} X &= X_1 + X_2 \\ &= \frac{N}{n} (x_1 + x_2) \\ &= N \frac{\bar{x}}{n} = N\bar{x} \end{aligned} \quad (46)$$

and

$$\text{var } \bar{x} = \left( \frac{1}{n} - \frac{1}{N} \right) \sigma_w^2, \quad \text{plan B.} \quad (47)$$

The  $n_i$  of eq. (44) and later expressions will not in general be integers. In practice one uses the closest integer; the effects on variance formulas are usually completely negligible.

*Plan C (Neyman sampling):* Decide with the help of eq. (49) the size,  $n$ , of the sample required. Compute next the Neyman allocation (Neyman 1934),

$$n_i = n P_i \sigma_i / \bar{\sigma}_w. \quad (48)$$

Draw by random numbers, as in plan A, a sample of size  $n$ , from stratum  $i$ . Investigate every member of the sample. Form estimators  $X_1$ ,  $X_2$ , and  $X = X_1 + X_2$ . Form  $\bar{x} = X/N$  for an unbiased estimator of  $a$ . Here

$$\text{var } \bar{x} = \frac{(\bar{\sigma}_w)^2}{n} - \frac{\sigma_w^2}{N}, \quad \text{plan C.} \quad (49)$$

The Neyman allocations are the optimal  $n_i$  for minimizing  $\text{var } \bar{x}$  when the  $P_i$  are known.

*$P_i$  known—only a sample classified.* One may, in appropriate circumstances, require only the classification of a preliminary sample drawn from the frame. The decision hinges on the costs of classification and the expected variances of the plans under consideration.

*Plan D:* Decide with the help of eq. (50) the size,  $n$ , of the sample required. Draw the sample as in plan A. Classify the sampling units into strata. The number,  $n_i$ , of sampling units drawn from stratum  $i$  will be a random variable. Carry out the investigation of every unit of the sample. Form  $X_1$ ,  $X_2$ ,  $X$ , and  $\bar{x}$  as in plan B. Then

$$\text{var } \bar{x} = \left( \frac{1}{n} - \frac{1}{N} \right) \left( \sigma_w^2 + \frac{1}{n} \sigma_n^2 \right), \quad \text{plan D.} \quad (50)$$

*Plan E:* Decide with the help of eq. (52) the size,  $n$ , of the final sample. Draw by random numbers a preliminary sample of size  $n'$ . Thin (reduce)

by random numbers the strata of the preliminary sample to reach the Neyman ratios

$$(51) \quad \frac{n_1}{n'_1} : \frac{n_2}{n'_2} : \dots = \sigma_1 : \sigma_2 : \dots$$

and simultaneously the total sample,  $n$ . Here  $n'_1$ ,  $n'_2$ , etc., are the sizes of the preliminary sample in the several strata, and  $n_1$ ,  $n_2$ , etc., are the sizes of the final sample. For greatest economy, choose  $n'$  so that one stratum will require no thinning. Carry out the investigation of every unit of the final sample. Form the estimators  $X_1$ ,  $X_2$ , and  $X = X_1 + X_2$ . Then  $\bar{x} = X/N$  will again be an unbiased estimator of  $a$ , but now

$$\begin{aligned} \text{var } \bar{x} &= \overbrace{\frac{(\bar{\sigma}_w)^2}{n} - \frac{\sigma_w^2}{N}}^{\text{plan C}} + \frac{1}{n} \left( \frac{1}{n'} - \frac{1}{N} \right) \bar{\sigma}_w \bar{\sigma}_n \\ &\approx \frac{1}{n} \left[ (\bar{\sigma}_w)^2 + \frac{1}{n'} \bar{\sigma}_w \bar{\sigma}_n \right], \quad \text{plan E} \end{aligned} \quad (52)$$

the latter form useful if  $N$  is large relative to  $n'$ .

*Sequential classification of units into strata.* We now describe two plans in which the sample-sizes,  $n_i$ , are reached sequentially, with considerable saving under appropriate conditions.

*Plan F:* Determine the desired sample-sizes,  $n_i$ , as in plan B. Draw by random numbers one unit at a time from the frame, and classify it into its proper stratum. Continue until the quotas,  $n_i$ , are all filled. Form  $X$  as in plan B;  $\text{var } \bar{x}$  will be the same as for plan B.

*Plan G:* This is the same as plan F except that the sample sizes,  $n_i$ , are fixed as in plan C. Form  $X$  as in plan C;  $\text{var } \bar{x}$  will be the same as for plan C.

*$P_i$  not known in advance.* When the proportions,  $P_i$ , in the frame are unknown, estimates thereof must come from a sample, usually a preliminary sample of size  $N' > n$ , where  $n$  is the size of the final sample.

*Plan H:* Decide with the help of eq. (55) the size,  $n$ , for the final sample. Compute the optimum size,  $N'$ , of the preliminary sample by the formula

$$(53) \quad \frac{n}{N'} = \frac{\sigma_w}{\sigma_b} \sqrt{\frac{c_1}{c_2}},$$

where  $c_1$  is the average cost of classifying a sampling unit in the preliminary sample, and  $c_2$  is the average cost of the final investigation of one sampling unit.

The procedure is to draw as in plan A a preliminary sample of size  $N'$  and to classify it into strata. Treat the preliminary sample as a frame of size  $N'$ . Then thin all strata of the preliminary sample proportionately to reach the final total size,  $n$ .

Carry out the investigation of every sampling unit in the final sample. An unbiased estimator of  $\alpha$  is

$$(54) \quad \bar{x} = \frac{x}{n},$$

where  $x$  is the total  $x$ -population in the sample. Then

$$(55) \quad \text{var } \bar{x} \approx \frac{\sigma_w^2}{n} + \frac{\sigma_b^2}{N'} = \frac{\sigma^2}{N'} + \left( \frac{1}{n} - \frac{1}{N'} \right) \sigma_w^2,$$

plan H,

is an excellent approximation if  $N$  be large relative to  $N'$ .

*Plan I:* Decide with the help of eq. (59) the size,  $n$ , for the final sample. Compute the optimum size,  $N'$ , of the preliminary sample, using the equation (Neyman 1938)

$$(56) \quad \frac{n}{N'} = \frac{\bar{\sigma}_w}{\sigma_b} \sqrt{\frac{c_1}{c_2}}.$$

Draw as in plan A a preliminary sample of size  $N'$ . Classify it as in plan H. Thin the strata differentially to satisfy the Neyman ratios

$$(57) \quad \frac{n_1}{N'_1} : \frac{n_2}{N'_2} : \dots = \sigma_1 : \sigma_2 : \dots$$

and to reach the desired final total sample-size,  $n$ . Carry out the investigation of every sampling unit in the final sample. An unbiased estimator of  $\alpha$  is

$$(58) \quad \bar{x} = \frac{1}{N'} \left( \frac{N'_1}{n_1} x_1 + \frac{N'_2}{n_2} x_2 \right),$$

for which

$$(59) \quad \text{var } \bar{x} \approx \frac{(\bar{\sigma}_w)^2}{n} + \frac{\sigma_b^2}{N'}, \quad \text{plan I,}$$

is an excellent approximation if  $N$  be large relative to  $N'$  and to  $n$ .

One may use plan F or plan G in combination with plan H or plan I to reap the benefit of many strata without actually classifying the entire preliminary sample,  $N'$  (Koller 1960).

*Gains of stratified sampling.* Gains of stratified sampling can be evaluated by comparing variances. Denote by  $A$ ,  $B$ , and  $C$  the variances of the estimators of  $\alpha$  calculated by the plans A, B, and C. Then

$$(60) \quad \frac{A - B}{A} = \frac{\sigma^2 - \sigma_w^2}{\sigma^2} = \frac{\sigma_b^2}{\sigma^2} = \sum_{i < j} P_i P_j \left( \frac{a_j - a_i}{\sigma} \right)^2,$$

$$(61) \quad \frac{B - C}{B} \approx \frac{\sigma_w^2 - (\bar{\sigma}_w)^2}{\sigma_w^2} = \sum_{i < j} P_i P_j \left( \frac{\sigma_j - \sigma_i}{\sigma_w} \right)^2.$$

For example, if  $P_1 = .6$ ,  $P_2 = .4$ , and  $\sigma_w^2 = .8\sigma^2$ ,  $(A - B)/A$  would be  $(1 - .8)/1 = .2$ , meaning that 100 interviews selected according to plan B would

give rise to the same variance as 125 selected according to plan A.

The gains of plans F and G over plan A are the same as the gains of plans B and C over plan A. The average gains in repeated trials of plans D and E are less. If  $\sigma_R^2$  and  $\bar{\sigma}_w \bar{\sigma}_R$  are large, plans D and E will usually not be good choices. For large samples, however, in circumstances where  $\sigma_R^2$  and  $\bar{\sigma}_w \bar{\sigma}_R$  are not large, the gains of plans D and E may be almost equal to the gains of plans B and C, at considerably less cost.

Eqs. (60) and (61) show that the gain to be expected from the proposed formation of a new stratum,  $i$ , will not be impressive unless its proportion,  $P_i$ , be appreciable, or unless its  $\sigma_i$  or its  $a_i$  be widely divergent from the average.

*Stratification to estimate over-all ratio.* The case to be used for illustrating stratified sampling to estimate an over-all ratio consists of three strata: stratum 1 for large units (for example, high incomes or large farms), stratum 2 for medium-sized units, and stratum 3 for small units. Here stratum 1 is to be covered 100 per cent; obvious modifications take care of the case in which stratum 1 is not sampled completely.

First take as an estimator of  $\phi$

$$(62) \quad f = \frac{X}{Y} = \frac{A_1 + N_2 \bar{x}_2 + N_3 \bar{x}_3}{B_1 + N_2 \bar{y}_2 + N_3 \bar{y}_3},$$

in the notation of tables 1 and 2, with  $B_i$  as the value of the  $y$ -characteristic in stratum  $i$  of the frame. Optimum allocation to strata 2 and 3 is very nearly reached if both

$$(63a) \quad n_2 = \frac{B_2 s_2}{B_2 s_2 + B_3 s_3}$$

and

$$(63b) \quad n_3 = \frac{B_3 s_3}{B_2 s_2 + B_3 s_3},$$

wherein  $s_2$  and  $s_3$  are the standard deviations of the ratio of  $x$  to  $y$  in strata 2 and 3.

If, as is often the case,  $s_2$  and  $s_3$  do not differ much, or if little is known about them in advance, one can still make an important gain in efficiency by setting  $n_2 : n_3 = B_2 : B_3$  or  $n_2 : n_3 = A_2 : A_3$ .

Another estimator of the ratio  $\phi$  is

$$(64) \quad f = P_1 f_1 + P_2 f_2 + P_3 f_3,$$

wherein  $P_i = B_i/B$  and  $f_i = \bar{x}_i/\bar{y}_i$ . This estimator is sometimes preferred when  $f_i$  varies greatly from stratum to stratum, and when there can be no trouble with small denominators. The allocation of sample for this estimator is, for practical purposes, the same as in eq. (63) (Cochran [1953] 1963, p. 175; Hansen et al. 1953, vol. 1, p. 209).

*Sequential adjustment of size of sample.* It is sometimes possible, when decision on the size of sample is difficult, or when time is short, to break the sample in advance into two portions, 1 and 2, each being a valid sample of the whole frame. Portion 1 is definitely to be carried through to completion, but portion 2 will be used only if required. This may be called a two-stage sequential method. It is practicable where the investigation is to be carried out by a small number of experts that will stay on the job as long as necessary but not where a field force must be engaged in advance for a definite period.

*Modifications for differing costs.* If investigating a sampling unit in a particular stratum is three or more times as costly as the average investigation, it may be wise to decrease the sample in the costly stratum and to build up the sample in other strata (Deming 1960, p. 303).

*Considerations for planning.* In order to plan a stratified sample, certain assumptions are necessary. Fair approximations to the relevant ratios, such as  $\sigma_w : \sigma$ ,  $\sigma_{w_0} : \sigma$ ,  $\sigma_{w_1} : \sigma$ ,  $\sqrt{c_1} : c_2$ , will provide excellent allocation. On the other hand, bad approximations to these ratios, or failure to use theory at all, can lead to serious losses.

The required good approximations to these ratios may come from prior experience, or from probing the knowledge of experts in the subject matter. For example, the distribution of intelligence quotients in the stratum between 90 and 110, if rectangular, would provide  $\sigma^2 = (110 - 90)^2/12$ , or 33, whence  $\sigma = 5.7$ . Other shapes have other variances, but shape is fortunately not critical (Deming 1950, p. 262; 1960, p. 260). A stratum with very high values should be set off for special treatment and possibly sampled 100 per cent.

*Stratification for analytic studies.* As mentioned earlier, the aim in an analytic study is to detect differences between classes or to measure the effects of different treatments.

The general formula for the variance of the difference between two means,  $\bar{x}_A$  and  $\bar{x}_B$ , derived from independent samples of sizes  $n_A$  and  $n_B$  drawn by random numbers singly and without stratification from, for example, two groups of patients, A and B, is

$$(65) \quad \text{var}(\bar{x}_A - \bar{x}_B) = \sigma_A^2/n_A + \sigma_B^2/n_B,$$

wherein  $\sigma_A^2$  and  $\sigma_B^2$  are the respective variances between the patients within the two groups.

For such analytic studies the optimum allocation of skill and effort is found by setting

$$(66) \quad \frac{n_A}{n_B} = \frac{\sigma_A}{\sigma_B} \sqrt{\frac{c_B}{c_A}},$$

wherein  $c_A$  and  $c_B$  are the costs per case. Note that the sizes of the groups do not enter into this formula and that it is different from the optimum allocation in enumerative problems.

In many analytic studies  $\sigma_A$  and  $\sigma_B$  will be about equal, and so will the costs  $c_A$  and  $c_B$ . In such circumstances, the best allocation is

$$(67) \quad n_{.1} = n_{.2}.$$

### Regression estimators

We have already seen reduction in variance resulting from use of prior or supplementary knowledge concerning the frame. Use of prior knowledge of  $N$  to form the estimator  $X = N\bar{x}$  is an instance. Prior knowledge of  $B$  to form the ratio estimator is another instance. This section, on *regression estimators*, describes other ways to use prior or supplementary knowledge concerning the frame. Regression estimators include the simple estimator,  $\bar{x}$ , and the ratio estimator,  $fb$ , as special cases, but they also include many other estimators, some of them highly useful. Like the ratio estimator of a total, these additional estimators are applicable only if independent and fairly reliable information is available about the  $y$ -population in the frame. Any estimator that takes advantage of supplementary information may have considerable advantage over the simple estimator,  $\bar{x}$ , if the correlation,  $\rho$ , between  $x_i$  and  $y_i$  is high, but this condition is not in itself sufficient.

*Specific forms of regression estimators.* Assume simple random selection and write the regression estimator in the form

$$(68) \quad \bar{x}_i = \bar{x} + m_i(b - \bar{y}),$$

wherein  $b$  is known independently from some source such as a census. The subscript  $i$  on  $\bar{x}_i$  here differentiates the several specific forms of regression estimators.

Regression estimators are closely allied with the analysis of covariance [see LINEAR HYPOTHESES, article on ANALYSIS OF VARIANCE]. The four cases to be considered here are taken largely from Hansen, Hurwitz, and Madow (1953).

*Simple estimator.* If  $m_i$  is taken as zero, the regression estimator obtained is  $\bar{x}_i = \bar{x}$ , seen earlier. This procedure makes no use of supplemental information. Under the assumption that  $N$  is large relative to  $n$ , the variance of this estimator is

$$(69a) \quad \text{var} \bar{x}_i = \sigma_x^2;$$

likewise,

$$(69b) \quad \text{var} \bar{y}_i = \sigma_y^2.$$

*Difference estimator.* The estimator  $\bar{x}_2$ , often called the difference estimator, is practicable if

Table 4 — Rel-variances when estimator of  $b$  is subject to sampling error

Estimator	Case I: sample of size $n$ is drawn as a subsample of $n'$	Case II: samples of size $n$ and $n'$ are independent
	Same as in Case I	Same as in Case I
$\bar{x}_1$	$C_y^2$	$C_y^2$
$\bar{x}_2$	$C_y^2[1 - \rho^2(1 - e^2)(1 - n/n')]$	$C_y^2[1 - \rho^2(1 - e^2) + \rho^2(1 + e)^2 n/n']$
$\bar{x}_3$	$C_y^2[1 - \rho^2(1 - n/n')]$	Same as in Case I
$\bar{x}_4$	$C_y^2 - (2\rho C_x C_y - C_y^2)(1 - n/n')$	$C_y^2 - (2\rho C_x C_y - C_y^2)(1 - n/n') + (2C_y n/n')(C_y - \rho C_x)$

prior knowledge (such as prior surveys of a related type) provides a rough approximation to the regression coefficient  $\beta = \rho\sigma_x/\sigma_y$ . This estimator is

$$(70) \quad \bar{x}_2 = \bar{x} + m_2(b - \bar{y}),$$

where  $m_2$  is any approximate slope not derived from the sample under consideration. The variance of  $\bar{x}_2$  is

$$(71) \quad \begin{aligned} \text{var } \bar{x}_2 &= \sigma_x^2(1 - \rho^2) + \sigma_y^2(m_2 - \beta)^2 \\ &= \sigma_x^2(1 - \rho^2 + \rho^2 e^2), \end{aligned}$$

where  $\beta = \rho\sigma_x/\sigma_y$  and  $e = (m_2 - \beta)/\beta$ . (Note that  $\rho e = (\sigma_y/\sigma_x)(m_2 - \beta)$  even if  $\rho = 0$ .)

*Least squares regression estimator.* If  $m_1$  is chosen as

$$(72) \quad m_1 = \frac{\sigma_{xy}}{\sigma_x^2} = \rho \frac{\sigma_y}{\sigma_x},$$

then the equation

$$(73) \quad \bar{x}_3 = \bar{x} + m_3(b - \bar{y})$$

gives the so-called least squares regression estimator. The variance of this estimator is

$$(74) \quad \text{var } \bar{x}_3 = \sigma_x^2(1 - \rho^2) + R.$$

Here  $R$  is a remainder in the Taylor series involving  $1/n^2$  and higher powers; this remainder will be negligible if  $n$  is large.

*Ratio estimator.* If  $m_4$  is chosen as

$$(75) \quad m_4 = \bar{x}/\bar{y} = f,$$

the ratio estimator is

$$(76) \quad \bar{x}_4 = f\bar{b}.$$

The variance of  $\bar{x}_4$  is

$$(77) \quad \text{var } \bar{x}_4 = \sigma_x^2(1 + C_y^2/C_x^2 - 2\rho C_y/C_x) + R',$$

$R'$  being another remainder. For large  $n$  and for  $C_x \approx C_y$ ,

$$(78) \quad \text{var } \bar{x}_4 \approx 2\sigma_x^2(1 - \rho).$$

It follows that for large  $n$  and for  $m_2 \approx \beta$  and  $C_x \approx C_y$ ,

$$(79) \quad \frac{\text{var } \bar{x}_4}{\text{var } \bar{x}_2} \approx \frac{2}{1 + \rho}.$$

*Comparison of regression estimators.* If the correlation,  $\rho$ , between  $x_i$  and  $y_i$  is moderate or high,

but the line of regression of  $x$  on  $y$  misses the origin by a wide margin, then the estimator  $\bar{x}_3$  will show substantial advantages over  $\bar{x}_4$  and  $\bar{x}_1$ . If the  $y$ -variate shows relatively wide spread (that is, if  $C_y$  is much greater than  $C_x$ ), the ratio estimator  $\bar{x}_4$  may be far less precise than the simple estimator  $\bar{x}_1 = \bar{x}$ , even when  $\rho$  is high, especially if the line of regression misses the origin by a wide margin. On the other hand, if the line of regression passes through the origin ( $\rho C_x = C_y$ ), or nearly through it,  $\bar{x}_3$  and  $\bar{x}_4$  will have about the same variance, but  $\bar{x}_1$  may be much easier to compute.

*Estimator of  $b$  subject to sampling error.* It often happens that the  $y$ -population per sampling unit is not known with the reliability of a census but comes instead from another and bigger sample. This circumstance introduces additional terms into the variances. Let  $n$  be the size of the present sample and  $n'$  the size of the sample that provides the estimate of  $b$ . We suppose that the variance of this estimate of  $b$  is  $\sigma_b^2/n'$ . The resulting variances of the regression estimators are shown in Table 4.

## II

## NONPROBABILITY SAMPLING

Nonprobability sampling refers to the selection of sampling units for a statistical study according to some criterion other than a probability mechanism. In contrast to probability sampling, nonprobability sampling has two major disadvantages: (1) the possibility of bias in the selection of sampling units and (2) the impossibility of calculating sampling error from the sample.

The attitude toward sampling held by most social scientists has come full circle: whereas it was once necessary to argue strenuously the case for deliberately using a probability mechanism in the selection of material for study, that case is now so widely accepted that any nonprobabilistic sampling procedure is regarded with suspicion. It will be argued here that such suspicion is generally well founded but that it is not to be equated with condemnation, since there are occasions when nonprobability sampling is the only procedure open to the investigator.

The issues involved in nonprobability sampling may be sharply focused by considering first the status of the inferences made by an archeologist. He can usually expect to find only a fraction of the material that he would like in order to examine the causes and motives of past events, and that fraction will generally be small for remote periods. Every object that he would judge relevant is a potential witness in his court of inquiry, but many of them have long since been destroyed or lost. Yet there is no contradicting the fact that some strongly convincing arguments can be made, even about the remote past. Does it follow, then, that probability sampling is inessential to any social scientist's inferences about the present?

As soon as it is drawn, this analogy is seen to be false. The archeologist usually has no choice;

he must, in the court metaphor, accept what witnesses offer themselves. The situation of another social scientist is different: he is rather in the position of having too many potential witnesses, among whom he must choose on grounds of cost and time. How is he to choose? He cannot fairly exclude those potential witnesses whose evidence may not be to his taste, for if he did, he would implicitly abandon his judicial position and become merely an advocate. (The fact that some have apparently undergone this transformation is not good reason for others to follow them.) If some sources of evidence must be chosen in preference to others, they can only conscientiously be chosen in some way unrelated to the nature of their evidence: they must be selected by a probability mechanism.

The value of probability sampling is, therefore, not that it ensures employment for statisticians, but that it provides a guarantee of freedom from selection bias on the part of the investigator, bias that may be strong even if quite unconsciously produced (Yates [1949] 1960, chapter 2). The absence of selection bias is the first advantage of probability sampling.

Nonprobability sampling always has the characteristic that the sampling procedure is ill-defined. One literally cannot know what chance of selection any individual in the population has had. It is this lack of precise definition that leads directly to the second disadvantage of nonprobability sampling: there is no way of estimating the sampling error of a nonprobability sample from the sample itself, while such estimation is typically possible when probability sampling is used.

Despite what has just been said, nonprobability samples will always be important in the social sciences. Confronted with a remote and hostile tribe, the anthropologist will not be inclined to imperil his foothold of hospitality and cooperation by selecting informants at random. In advanced societies, selected individuals or institutions may refuse to cooperate in an inquiry and usually cannot be compelled to do so. Even in such circumstances, however, at least an attempt at a probability sample should always be the investigator's object. He may fail to achieve it but cannot be worse off than if he had not tried at all. The unshakable optimism of all candidates for political office must be partly attributed to reports from supporters who have largely been sampling the faithful.

Nonprobability samples can arise in several ways: through the investigator's ignoring or denying the force of the above considerations; through his recognizing their force but claiming that the

objectives of probability sampling can just as well be achieved by substitute methods; or finally, through his lack of success in attempts to achieve probability samples. About the first category nothing more will be said here, but a more detailed examination of the other two will be made.

**Representative methods.** Most of the substitutes suggested for probability sampling have in common some attempt to make the sample "representative" of the population from which it was selected, for example, by arranging that the proportions of men and women be the same in both or (more rarely) that the average income be the same in both. In practice, the most frequent substitute is quota sampling (Moser 1952), in which distributions by sex, age, "class," and sometimes additional characteristics are equalized between sample and population and the interviewers are otherwise free to select cases. Such representative methods are to be sharply distinguished from stratified probability sampling, where the population is divided into groups prior to sampling and each group is sampled separately by probability methods.

There are several distinct criticisms to be made of representative procedures. In the first place, the agreement of even quite a large number of averages or percentages between sample and population in no way guarantees high accuracy in other respects, and very large biases are still possible (Neyman 1934). Second, the lack of definition in the sampling procedure is not corrected by the imposition of such agreements; sampling error is still not calculable.

The most important criticism, however, is a paradoxical one. There is no such thing as a "representative," "unbiased," "fair," or otherwise "acceptable" sample: such adjectives are strictly applicable to the sampling process that produces the sample, and their application to the sample itself is at best a piece of verbal shorthand and at worst a sign of muddled thinking. A sample can be judged only in relation to the process that produced it. The central concepts of selection bias and sampling error have no meaning except in this context (Stuart 1962). Thus, an ill-defined sampling process, such as is involved in nonprobability samples, can only produce a sample with ill-defined properties of bias and sampling error.

**Embedding in a probability framework.** The statement that there is no way of calculating sampling error for nonprobability samples is always true but can be made irrelevant by the device of embedding a nonprobability sampling procedure within a higher-order probability framework. Suppose that a nonprobability sampling procedure is proposed in which 1,000 families are to be inter-

viewed in a certain area and that ten interviewers are to be used. If each interviewer is independently given an assignment to interview 100 families by identical methods, there will be not one, but ten nonprobability samples, and the variation among the results of these ten samples may be used to estimate the sampling error attached to a sample of 100 families and thence, by a natural extension, to estimate the error for a sample of 1,000 families. Since the sample is designed as ten equivalent independent subsamples, in effect the sampling is of ten members from the population of all possible samples obtainable by that method with those interviewers.

In practice, it may be difficult or practically impossible to achieve independent subsamples in some contexts. For example, in the construction of index numbers the choice of commodity items is usually made by a panel of experts, so that the items chosen constitute a nonprobability sample. If an attempt is made to measure the variation between the judgments of several experts at the same level of expertise, interaction phenomena that make the measurement difficult are immediately encountered. For example, the experts are likely to have consulted one another; they are likely to know the criteria of selection used by their peers; they are bound to meet in the course of examining files containing background information, and so on. Thus, although independent judgments are in principle possible, the practical problem of arranging for independence is very difficult. Now, almost certainly, in the simple interviewing example, differences between the interviewers will affect the results of the survey (through personal characteristics, differences in thoroughness, etc.), and such differences will inflate the sampling error when it is estimated as above. If it were important to eliminate differences between interviewers from the sampling error, a slight modification in sampling design would suffice. Each interviewer must be asked to carry out at least two independent sample assignments, say four assignments of 25 families each. It will then be possible, by exactly the same argument as before, to estimate variability "within interviewers" only, thus excluding variability "among interviewers" from sampling error estimates. Further improvements in design are also possible. [See INDEX NUMBERS, *article on SAMPLING*.]

It will be seen that nonprobability sampling treated in this way utilizes the theory of experiment design, and, as always in that subject, care is necessary to ensure that assignments are allocated at random to interviewers. An incidental

advantage of such experiment designs, which is often of greater practical importance than the original purpose of estimating sampling error, is that they make it possible to see whether interviewers are varying so much in performance that further training or other action is called for.

Such evidence as is available from designs of this sort indicates (Moser & Stuart 1953; Stephan & McCarthy 1958) that the sampling errors of quota sampling are considerably larger than those of comparable probability sampling. (If sampling is multistage, the inflation will of course only apply to the stage or stages at which quota sampling is used—this is commonly the final stage only.) Quota sampling can therefore only be justified, if at all, on grounds of reduction of costs, but it is doubtful whether, in the light of current cost structures, this factor is large enough to offset the excess sampling error of quota sampling. Some crude numerical guide is contained in the introduction to the tables by Stuart (1963).

Of course, experiment designs of this sort may be used with any ordinary probability sampling scheme (Mahalanobis 1946). The point here is that experiment designs rescue nonprobability sampling schemes from one of their worst deficiencies, the impossibility of calculating sampling error estimates, which does not hold for probability sampling. Nothing, however, can rescue nonprobability sampling from the ever-present danger of selection biases, a danger particularly acute for those forms (like quota sampling) that allow considerable freedom to interviewers to select cases.

Taken in conjunction with the sampling error and cost considerations, the bias danger suggests that, whatever may have been the case when it originated, quota sampling is now, in terms of reliable information delivered per unit cost, uneconomical as well as anachronistic.

**Incompletely achieved probability samples.** It has been noted that the major unremovable drawback of nonprobability samples is the danger of bias in the selection procedure. Inevitably, this danger must also arise when an intended probability sample is, through lack of cooperation, through inaccurate fieldwork, or through accidentally missing records, reduced to a fraction of the number of cases originally selected. The selected sample is, for one or another of these reasons, incompletely achieved, and the sampler's duty is to survey the damage done to his original plan and try to assess the importance of the danger to his purposes. Strictly speaking, an incompletely achieved probability sample ceases to be a probability sample, although it usually continues to be

called one. Intentions are not the same as achievement, and the sampler must see whether the courtesy title is deserved.

Before discussing what can be done in such situations, it is useful to compare the reaction of the probability sampler confronted by an incompletely achieved sample with that of the nonprobability sampler in the same position. It is an empirical fact that the probability sampler is usually much more worried about the incomplete sample than is the nonprobability sampler, because the stringency of a probability sampling scheme draws much greater attention to any weaknesses in the achieved sample. By contrast, the nonprobability sampler usually finds it easier to bring his sample numbers up to the required level. His sampling scheme is less stringent and can more easily be patched up. Advocates of nonprobability sampling (principally quota sampling) have been known to categorize this as an advantage for their method, but we shall take the contrary view. It is because nonprobability sampling is so ill-defined that its definition can be extended to cover incomplete sample fulfillment. In the kingdom of the one-eyed, the blind man is less easily seen. Perhaps the least appreciated, because it is the most troublesome, feature of probability sampling is the urge for sample completeness that it imposes upon its practitioners.

Faced with a seriously incomplete sample, the probability sampler will usually redouble his efforts, but however hard he tries, he will ultimately have to face the fact that some part of his sample is not to be completed. The characteristic rates of noncompletion vary greatly with types of sample. For probability samples of individuals in the United Kingdom, it is possible to achieve completion rates of 90 per cent, although 80 per cent is nearer the general average. For probability samples of households in United Kingdom government household-budget inquiries, the completion rates range around 70 per cent. Few surveys involve a more onerous burden upon the respondent than the keeping of a detailed household budget, so it is probably reasonable to state that completion rates in the United Kingdom should never, with careful fieldwork, fall below about 70 per cent. The range of noncompletion rates likely to be encountered is thus of the order of 10 to 30 per cent. For many purposes, the sample results will not be seriously biased by even a noncompletion rate of one-quarter. For example, if 60 per cent of all households in the completed three-quarters of the sample display a certain characteristic, the non-completed quarter of the sample would need to

have under 40 per cent or over 80 per cent with that characteristic for the bias in the completed sample to exceed 5 per cent.

The crucial question to be examined in assessing the likely magnitude of bias due to incompleteness is whether the causes of incompleteness are related to the questions of interest. In a study of women's cosmetics usage, it would be running a serious risk to ignore a very low completion rate for teen-agers, who are particularly heavy users of cosmetics; if the completed sample showed a very low percentage of teen-agers compared with the selected sample (or known recent population data), special efforts would have to be made to increase that percentage. But if the completed sample showed an excess of women aged 45-55 and a shortage of women over 65, this would be unlikely to exert a significant influence on cosmetics-usage findings. However, if the subject studied were demand for domestic help, it would be the shortage of the elderly that would be the threat. Data from published population figures or from specially undertaken supplementary probability samples can often be used to check and, with appropriate methods of statistical analysis, to improve estimates suspected of bias, whether it is due to sample incompleteness or not (Moser & Stuart 1953; United Nations 1960, sec. 13). The simple examples just given show that such check data can only be used in conjunction with the experienced judgment of the investigator. If extreme imbalances of the completed sample are revealed, they are just cause for suspicion of the sample results, but the converse does not hold: no finite amount of external checking of this kind can ever fully validate a nonprobability sample, since the crucial variable to check may be overlooked or not checkable. There is no completely satisfactory substitute for a fully achieved probability sample. Any shortfall from this status is a potential threat to the inferences drawn from the sample. The investigator may be able to judge in some cases that the threat is not likely to be serious, but he can do no more than this. Insofar as a probability sample is fully achieved, it obviates the need to make such judgments.

To return to the first analogy, it can now be seen that the archeologist is in a situation closely resembling that of the investigator with an incomplete nonprobability sample. Another social scientist can usually improve on this situation at least to the extent of starting with a probability sample of his material. The incompleteness of his sample may on occasion compel him to make judgments

of an inconclusive kind about the quality of his sample, but this is not a valid reason for extending the scope of the inconclusive judgment to the whole sampling procedure.

## SANCTIONS

Social control involves the process by which a group perpetuates its culture and system of social relations. In what has become an anthropological *locus classicus*, Radcliffe-Brown (1934) defined the sanction as a social reaction to a mode of behavior that was thereby approved or disapproved. In his view the concept is of primary significance to sociology because sanctions provide an effective instrument for regulating conduct in conformity with social usage. This formulation, however, seems to obscure a number of important points. Radcliffe-Brown's argument clearly implies that the sanction, at least in one of its aspects, has a deterrent function. But if this object is to be achieved, logic demands that the sanction must precede the reaction: the sanction must already be in operation when a breach of norm occurs. It seems preferable therefore to define sanctions in terms of a promise of reward for fulfillment of the norms of behavior that are socially recognized and accepted, or in the liability to suffer the consequences that attend their breach. According to this view, the sanction is thus characterized by a quality of latency that is expressed most clearly, in the case of negative sanctions, in a general belief in the continuing likelihood of the execution of the threat. This implies two further properties of the sanction. A sanction cannot be arbitrary or *ad hoc*: its existence must be generally known, and it must be regular in its incidence. In fulfilling these conditions, the sanction serves not merely to deter; it also indicates the appropriate steps that may be taken to redress the situation when a norm has been infringed or to express approbation when it has been overfulfilled.

The sanction is, of course, a concept of funda-

mental importance in jurisprudence and has played a paramount role in different legal theories. But there seems no good reason why its use should be restricted in this way. The legal sanction, manifested in the form of the penalties, remedies, and modes of redress of the law, represents only one particular means of enforcing conformity to norms and restating their validity when they are breached. Each group and subgroup within a society tends to develop its own distinctive pattern of usages and the means of maintaining them without necessary recourse to the municipal law. Sanctions therefore come to operate within every conceivable set of group relationships: they include not only the organized sanctions of the law but also the gossip of neighbors or the customs regulating norms of production that are spontaneously generated among workers on the factory floor. In small-scale communities, or within segments of a large-scale society, informal sanctions may become more drastic than the penalties provided for in the legal code. Thus the concept of sanctions is not merely of jurisprudential interest; it also has immediate sociological relevance to the analysis of the problem of social control.

It will be apparent then that social control is achieved through no single mechanism. On the contrary, different principles and processes will frequently be found working together in any given situation. Accordingly, it is only by specifying the character of the sanctions present in the situation that one can isolate the different elements for analytical purposes and give them their proper weighting. The institution of law represents, of course, one major instrument of social control, and it is most usually marked off from other such agencies by virtue of the fact that its sanctions are

imposed by politically organized society. As Seagle (1941) has observed, for example, it is the fact that the sanction is applied exclusively by organized political government that distinguishes the sphere of law from the spheres of religion, morals, and custom.

**The mechanism of sanction.** The differentiation of the instruments of social control in stateless and state societies and in peasant communities and bands of hunting and gathering people has provided ground for controversy between jurists and anthropologists and among anthropologists themselves. Although their discussions have not always clarified the nature of law in different types of societies, they have been fruitful in opening up the broader sociological problem of social control. Malinowski's position as a pioneer in this field remains undisputed. Working in an island society that lacked any of the familiar machinery for the enactment, administration, and enforcement of law, Malinowski was led to seek elsewhere for the sources of social cohesion. He came to the conclusion that there was a class of rules "too practical to be backed up by religious sanctions, too burdensome to be left to mere goodwill." This constituted the Trobriand "civil law," the binding character of which lay in the sanctions of reciprocity and systematic incidence (Malinowski 1926). Later critics have pointed out that reciprocity is a concept of such wide generality that it cannot usefully serve to delineate the sphere of law. A curious feature of Malinowski's thinking on these matters is that, despite his emphasis on conflict, he appears not to have appreciated that just as the sanction implies the potential breach of norm, so much of law has to be concerned with what may be called the "pathology" of social relations. The emphasis on reciprocity has been important in deepening our understanding of why rules of behavior are accepted in so many areas of social life without the need to resort to formal mechanisms of redress. The question that remains unanswered is what happens when reciprocity breaks down and breach actually occurs. The point had been raised often enough, but it was left to Llewellyn and Hoebel (1941) in their now classic study of the Cheyenne to repair the defect and put the anthropological study of legal sanctions back on its proper path. In their succinct and expressive phrase, "the law has teeth": their procedure was to show that, even in societies lacking instituted juridical bodies, the investigation of instances of "hitch," dispute, grievance, and trouble led directly into the way in which physical coercion was organized.

Pospisil (1958), on the basis of his work among

Kapauku Papuans, has suggested that too great an emphasis has been placed upon physical force in defining the character of the legal sanction, pointing out that cultures exist where physical sanctions are practically lacking. This introduces an unnecessary confusion. The crucial question is not the actual mode of coercion employed but recognition of the legitimate authority in which is vested the power of coercion. Such authority is certainly recognized among the Kapauku, although coercion may frequently be achieved by other than purely physical means. Where, in a society lacking developed forensic institutions, rules of conduct may be enforced through the powers of coercion vested in a legitimate authority, I propose to speak of jural rather than legal sanctions, indicating that here we are in the realm of *ius*, but not of *lex*.

**Jural sanctions.** Once the criterion of legitimate coercion is adopted, it becomes apparent that primitive societies, lacking the formal machinery of the law, may yet display a remarkable range of sanctions that can be distinguished as jural. It has sometimes been claimed of many of the simplest societies that their social life is dominated by notions of the supernatural: there is a paucity of rules of law that is the reflex of the comprehensiveness of taboo. Such views, however, do not do justice to the facts. Thus it is reported of the Eskimo, for example, that persistent breach of taboo may be met by a shaman's decree of banishment. More strikingly, it is also reported that recidivist homicides may be dispatched by an individual acting at the request of the local community or with its compliance; this individual does not incur vengeance. Another interesting type of jural sanction was reported by Radcliffe-Brown in the Andaman Islands (1922). There, aggrieved persons were apparently able to vent their spleen by destroying any property they could lay their hands on, but unfortunately there are a number of points touching the operation of the sanction which the sources do not make very clear. It is possible that the Andamanese practice was somewhat similar to the custom of *hamara* reported from the Gazelle Peninsula of New Britain. *Kamara* took a number of variant forms, but essentially it was a device whereby a person who had suffered injury could damage or distrain the property of someone of acknowledged influence within the community. This individual was expected then to bring pressure on the offender to make retribution.

But in general, within the range of primitive societies, the most common mode of redress for wrong is found to rest on the principle of self-help. In these circumstances, the legal initiative lies in-

variably with the individual or group against whom a wrong has been committed. Yet the exacting of vengeance is not an arbitrary procedure. It has to be carried out according to certain rules and is undertaken only when morally supported by the community or because, indeed, it has been pressed upon individuals or groups by expressions of public approval or disapproval.

The principle of self-help involves a point of considerable importance for the discussion of sanctions. This is what Nadel (1947) has called the social range of offenses, where the kind of sanction provoked depends upon the nature of the social units involved in the offense. Thus, in some societies if adultery or homicide occurs within the local lineage it may be regarded more as a sin than as a legal wrong, calling for ritual expiation rather than the application of jural sanctions. If, however, it involves members of different clans within a larger political unit, the offense may be met by a punitive raid or may have to be compounded by payment of compensation. In other words, it is not enough to regard a given sanction simply as the appropriate response to, or mode of redress for, any particular offense. Rather the sanction has to be viewed as it pertains to the set of social relationships involved in any given situation and at a particular moment in time. Failure to see the sanction in these terms can lead to misconceptions and to misguided hypotheses of an either/or character, as in attempts, for example, to correlate the importance of sorcery with the presence or absence of "superordinate justice" (Whiting 1950). Formulations of this kind pose a false dichotomy; they also miss the point that because each individual is the focus of a number of different social relationships, combining in his person a number of different roles, a variety of sanctions may attach to a single act of behavior. Thus, to take an example from our own society, a member of one of the professions who commits a serious breach of professional etiquette faces the possibility not only of prosecution in the courts, but also of being struck off the roll; he may also find that he has sacrificed his position as chairman of the local literary and philosophical society and that his wife and children have lost the good will of friends and neighbors. In other words, there is in all societies a coincidence of sanctions, some of a jural, some of a mystical or other character, all operating simultaneously toward the goal of achieving social control. Thus the problem that has to be faced is only partly the clear demarcation of one kind of sanction from another; more important is the need to classify and analyze the typical situations in which

the different kinds of sanctions are provoked or achieve dominance.

**Analytic examples.** Some progress in examining the social context of sanctions has been made by Turner (1957) in an analysis of the conflicts operating within the social system of the Ndembu of Northern Rhodesia. Among the various redressive mechanisms known to the Ndembu are informal arbitration, formal courts under the control of chiefs, and certain kinds of public ritual. Turner has suggested that jural machinery is likely to be invoked when a dispute is conducted in terms of an appeal to common norms, or, alternatively, when the dispute itself involves an appeal to different or opposed norms, but it can still be settled fairly easily because there exists "a common frame of values which organize a society's norms into a hierarchy." There are, however, other kinds of conflict, which have their source in the contradictions inherent in the social structure itself. For example, when the rules of nepotic and adelphic succession both operate within a matrilineal system, they tend to promote faction within local groups. If these conflicts are not effectively sealed off, they may lead to the disruption of the group. For disputes of this kind, usually sparked by the breach of some legal or customary norm, jural sanctions are likely to be inappropriate and ineffectual. A court of law, employing rational techniques of inquiry, hears the arguments of the various parties and on its reading of the evidence proceeds to allocate blame to one or the other of the disputants. Such a procedure cannot "relieve the quarrels so as to preserve the threatened relationships." This explains why it is that among the Ndembu and other peoples of the central African "matrilineal belt" so few cases arising out of disputes within the matrilineage come before the tribal courts. These indeed are the kinds of situations par excellence in which the sanctions associated with accusations of witchcraft and sorcery or the wrath of ancestral spirits are predominant and where group unity can be reaffirmed only by ritual means. So, too, in modern Western society the invocation of legal sanctions may be found inadequate for the handling of certain kinds of domestic disputes. A court of law, by concentrating on husband and wife as right-bearing and duty-bearing units, excludes itself from examining a close and complex relationship in its totality; the less rigid techniques of a marriage guidance council or other similar agency may have to be invoked if reconciliation of the parties is the end to be achieved.

With the development of recognized courts, a new and important phase has been reached in the

eternal task of achieving social control. Once forensic institutions have been established, little comes to escape their purview, and there are few matters that may not be the subject of judicial scrutiny. Yet, perhaps for this very reason, it is important to remember, as the last example cited itself suggests, that adjudication may cover a range of different procedures. The distinguishing criteria of a court appear to be that it is capable of enforcing the principle of jurisdiction and that it is led to the apportionment of liability by the rational assessment of the evidence and arguments adduced before it.

In many African societies, informal hearings before village elders and the detection of the causes of personal and natural misfortune by divination share certain of the characteristics of the judicial process, but clearly it would be a mistake to equate them with courts. Similarly, as Gluckman (1962) argues, it seems a mistake to speak of the institutionalized song duels of the Eskimo as "juridical instruments" even though they do serve to settle disputes and restore normal relations between estranged members of the community. It may be true that the result of the contest is a "judgment" in favor of one of the contestants, but, so far as can be gathered from the literature, the mode of arriving at that judgment has little in common with a judicial process. Here a lack of clear analytical distinctions can blur the important sociological problem of why in different societies, or in different ranges of relationship within the same society, different kinds of sanctions may be invoked for similar kinds of breach of norm.

Nevertheless, the instance of the Eskimo song encounter does direct attention to a variety of sanctions occupying a borderland between the realms of law, morals, and custom. The literature on the song contest does not make clear how points are scored in the duel, nor does it indicate what part the spectators play in this connection. On the other hand, the fact that the contestants are obliged to accept the taunts, jibes, and accusations of their opponents without taking affront suggests parallels with forms of licensed "joking" familiar in the anthropological literature. There is, for example, the system of clan joking relationships described for the Plateau Tonga of Northern Rhodesia. Among the Tonga, the clans are the only enduring units of social organization, and they are linked in a complex arrangement of joking partnerships. The Tonga explain these relationships by reference to some antagonism between the animals from which the clans derive their names or to some legend of origin. Whenever members of such paired clans

meet, they tease one another and indulge in mutual abuse. Joking of this kind occurs in informal situations, but this, like the Eskimo song contests, which are conducted for pure entertainment, has to be seen as a necessary preparation of the stage, so to speak, for those more serious occasions when culturally licensed abuse may be employed as a public sanction. The jural unit of Tonga society is the matrilineal group, but there are many situations where this group is not free to act without destroying the very principle of lineage unity on which the social structure is built. Those who waste their kin's property or commit incest provide instances of this kind. Their offenses are, in a sense, jural wrongs; but they also touch questions of ultimate social morality. For the protection of the community, the sanction of public castigation and ridicule of the offender by his clan joking partner is invoked (Colson 1953). Institutions embracing the "joking" principle are widespread; and they are not confined to tribal societies. It appears that "youth groups" may perform a similar role in some of the rural communities of present-day Spain and Wales (see Peters 1967). Such groups, which initially establish their "irresponsibility" by playing childish pranks as part of their normal behavior, are on occasion able to express the outraged moral feelings of the community by playing offensive practical jokes on those who have offended but who cannot be readily reached by straightforward legal sanctions. These instances, incidentally, illustrate another important mechanism in the process of social control. This is the principle whereby the enforcement of the sanction is thrust upon a "stranger" to the group; it is used in situations involving the unity of the group rather than the claims of aggrieved individuals. Through the medium of the clan joking partners, or the youth group, who are strangers to the adult community by virtue of their customary infantile behavior, the fiction of group cohesion can be maintained and group norms reaffirmed.

**Function of integration.** The importance of the sanction lies, then, as Radcliffe-Brown noted (1934), in its integrative function. The social system is made up of many different kinds of groupings, frequently based on different principles of social organization and serving different sets of interests. Associated with these groupings and with the different and sometimes conflicting sets of social relationships in which their members are involved, there is a wide range of social sanctions, at the back of which are the organized sanctions of the law, supported by the coercive authority of society. Even in those systems where "legal totali-

tarianism" has been carried furthest, it is clear, as Lewin (1947) has documented with reference to South Africa, that social control is not achieved exclusively through the operation of the sanctions of the law. Faced with this problem, certain jurists have been led to postulate a "general habit of obedience" to explain why, everywhere in society, laws are more often obeyed than disobeyed. A sociological approach, on the other hand, would stress that the efficacy of law rests, in the final analysis, on the support it receives from the operation of non-legal sanctions in the various domains of social life.

We can see something of the way this process operates in some analyses of the judicial process in African tribal societies. Barotse judges, for example, had behind them the full power and authority of their nation as well as of the British colonial administration. In the handling of disputes, however, the sanctions of morality and custom and, indeed, the whole normative structure of the society are channeled into the judicial process itself. Litigants and judges alike appeal to, and couch their arguments in terms of, the same body of norms. When a man is condemned, it is usually because he has failed to measure up to the standards of behavior that he himself has invoked in his statements to the court (Gluckman 1955). It is, of course, patent that there are important differences between the judicial processes in African societies and those in modern Western societies. Unfortunately the classic studies of the judicial process in Anglo-American systems have concentrated on judicial reasoning in the upper levels of the judicial hierarchy or upon exposing the nonlegal influences that play upon the mind of the judge. What seems to be required for purposes of significant comparison is the more intensive sociological investigation of courts and other similar bodies at the lower levels of the hierarchy, in the context of the communities within which they operate. Such studies might prove to be very important in illuminating the way in which social norms and sanctions are brought into relationship with the legal system.

#### SANCTIONS, INTERNATIONAL

The term "sanction," in its widest sense, means "any measure taken in support of a social order regulating human behavior" (Kelsen 1957, p. 101). The purpose of a sanction is to bring about a behavior considered to be in conformity with the goals and standards of a society and to prevent that behavior which is inconsistent with these goals and standards. Consequently, in its widest sense, a sanction can have the objective of suppressing and terminating a particular form of undesirable behavior and the objective of deterring or discouraging such behavior in the future. The word "sanction" originated in Roman law, where it meant a penalty imposed upon a person who violates the law. The word continues to be used in this narrow

sense, particularly in municipal law. In international relations, the term is customarily used in the wider sense.

It is sometimes asserted, particularly with reference to Austin's definition of law, that international law is not law because it lacks the sanctions of municipal law. That there is a difference of degree is no doubt true, but what is often not recognized is that municipal law, like international law, is basically dependent upon custom and consent, while international law has sanctions comparable with those of municipal law, though admittedly weaker. The organization of sanctions in support of an international order faces a special difficulty not encountered within the state to anything like the same degree. This is the difficulty of enforcing standards against organized groups which, as states, make exclusive claims on governmental authority and on the loyalty and support of their citizens. Even within the state, constituted authorities experience difficulties in enforcing their decisions against organized groups such as trade unions and component political units, as witness the difficulties experienced by the organs of the federal government of the United States in enforcing their decisions against the states.

### Experience

Customary international law has in the past admitted the right of states to take certain measures of self-help in support of their legal claims if it was not possible to achieve satisfaction by negotiation or third-party settlement. These measures included withdrawal of diplomatic representatives, acts of reprisal such as embargo and pacific blockade, display of force, landing of armed forces for purposes of protection of persons and property, and resort to war. Under agreements concluded to meet particular situations, special guarantees were accorded and the right of intervention admitted, as, for example, in the collective guarantee of Belgian neutrality (1839) and the United States guarantee of Cuban independence (1901).

Under the Covenant of the League of Nations, the concept that peace should be maintained by the combined forces of peace-loving states was substituted for the principles of balance of power and self-help. "Resort to war" under defined conditions was prohibited. Provision was made under article 10 for joint guarantee of member states against external aggression and in article 16 for sweeping economic and financial sanctions to be applied "immediately" by every member against any state resorting to war in violation of its obligations under the Covenant. The Covenant provisions were seri-

ously weakened by resolutions adopted by the Assembly in 1921 that were intended to take account of the failure of the League to achieve universality. Military sanctions under the Covenant were optional on recommendation of the Council.

No serious consideration was given to the application of the sanctions of article 16 until the mid-1930s. The Japanese invasion of Manchuria in 1931 was not treated as a resort to war under the Covenant. The Assembly did, however, recommend to members that they withhold recognition of the fruits of Japan's military action, in line with the announced policy of the United States. This constituted a mild form of sanction, which had, however, no observable practical effect. In 1935, however, Italy's military invasion of Ethiopia was recognized by all except a small minority of members as an illegal resort to war, and limited economic and financial sanctions were applied. These were not adequate, however, to achieve the declared objective of frustrating Italy's military action, and leading members of the League were unwilling, for political reasons, to agree to measures that might have been effective.

The Charter of the United Nations adopts a different approach to the problem of sanctions. Like the Covenant, its objective is limited to the maintenance of peace; the Charter prohibits any threat or use of force against the territorial integrity or political independence of any state "or in any other manner inconsistent with the Purposes of the United Nations" (art. 2, paragraph 4). The sanctions envisaged, however, are not automatic, being left to the discretion of the Security Council. In cases of threats to the peace, breaches of the peace, or acts of aggression, it may take decisions requiring members to apply collective measures, including the severance of diplomatic relations, economic and financial nonintercourse, and "action by air, sea or land forces" (art. 42). But the taking of military measures is made dependent on the conclusion of agreements by which members undertake to place forces and facilities at the disposal of the Security Council (art. 43). In addition, a member against whom preventive or enforcement action has been taken may be suspended from "the exercise of the rights and privileges of membership" by the General Assembly upon the recommendation of the Security Council (art. 5), and a member who has "persistently violated the Principles" contained in the Charter may be expelled in like manner (art. 6). The Charter does not confer upon the General Assembly any explicit powers with respect to the imposition of sanctions. It does give to the Assembly the general authority to discuss and make

recommendations with respect to any matter within the scope of the Charter (art. 10).

In United Nations practice, the Security Council has largely been prevented from using its powers to apply sanctions—its enforcement powers—by the inability of the permanent members to agree. In the early stages of its handling of the Palestine question (1948) it specifically invoked these powers and threatened to use them. In the Korean case, the Council, in the absence of the Soviet representative, recommended assistance to the Republic of Korea and, under this authorization, members took measures of the kind described in articles 41 and 42. More recently, in dealing with policies of racial discrimination by South Africa, the Security Council, by its resolution of December 4, 1963, called upon members to refrain from shipping arms and munitions to that country so long as it practiced this discrimination, which it found was "seriously disturbing international peace and security."

The General Assembly, in the exercise of its broad powers under the Charter, has on numerous occasions recommended to members the adoption of various measures of a coercive nature to bring the conduct of particular states into line with standards set by the Charter, international law, and United Nations resolutions. Examples include such recommended measures as the withdrawal of heads of missions to Spain and its exclusion from UN conferences in order to eliminate the Franco regime (1946); an embargo on the shipment of arms and strategic materials in general to North Korea and Communist China to suppress their aggressive action (1951); and an embargo on export of arms and petroleum products to South Africa to achieve the termination of policies of racial discrimination (1963). The measures recommended by the General Assembly have had a range of purposes extending beyond the maintenance of international peace and security, to the implementation of obligations and policies in respect to self-determination and human rights.

Provisions for the application of international sanctions are not limited to the constitutions of global international organizations. The Inter-American Treaty of Mutual Assistance, for example, provides that in case of aggression by an American state, the Organ of Consultation may decide that the other signatory states apply sanctions, including political, economic, financial, and military measures. Decisions may be taken by a vote of two-thirds and are binding, except that no member can be required to use military force against its will. In August 1960, the decision was taken to sever diplomatic relations and partially interrupt

economic relations with the Dominican Republic because of its aggression against Venezuela.

### Evaluation

Experience with organized international sanctions in support of international order has been limited and does not give much encouragement to those who believe in the efficacy of such arrangements. The League system of sanctions was a system of collective security which rested "upon the proposition that war can be prevented by the deterrent effect of overwhelming power upon states which are too rational to invite certain defeat" (Claude 1964, p. 228). It also assumed that an ethical and legal difference existed between military force used by a state to advance its national interests and the use of force by members of an international organization to restrain a state after it has been adjudged guilty of illegal use of force. This experiment was handicapped from the beginning by the League's lack of universality. The limited economic and financial sanctions imposed against Italy showed that international sanctions were technically feasible. The necessary machinery could be organized and decisions could be taken to permit sanctions to become operative promptly and with substantial impact on the transgressor. Their failure was due to political difficulties—the conflicting interests and purposes of the sanctioning powers and the unwillingness of some states to risk war to make sanctions effective.

United Nations experience has not been encouraging either. Sanctions against Franco Spain were applied half-heartedly and were soon terminated. In the Korean case, the measures taken to assist the Republic of Korea and to defeat the aggressive actions of North Korea and Communist China were essentially United States measures dictated by United States policy considerations. The United Nations served as a useful framework to provide legitimacy and as a moderating influence. Measures recommended against South Africa to achieve fuller respect by that member for basic human rights have had little observable effect.

What conclusions are to be drawn from this and other experience regarding the role of international sanctions in the implementation of international order? Statesmen and scholars have arrived at a variety of conclusions.

One conclusion which appears to be widely held is that the theory of international sanctions, particularly as it involves the use of military force, is fallacious. According to this view, no effective pressure can be applied against a state except by another state, and consequently, an international

order that depends on that form of pressure is a permanent source of conflict instead of a medium of order. As early as 1787 Hamilton wrote in *The Federalist*: "In an association where the general authority is confined to the collective bodies of the communities that compose it, every breach of the laws must involve a state of war; and military execution must become the only instrument of civil obedience" (No. 15).

Another conclusion that has wide support is that forces of coercion which are effective when applied to individuals are not effective, at least not to the same degree, when applied to states. Even those forms which might be expected to be particularly effective, such as embargoes and blockades, may at least temporarily have the opposite effect. In the case of the economic sanctions against Italy, among the immediate effects was a strengthening of popular support for the regime.

A view which is widely held by those who stress national interest as the motivating force in international relations is that international sanctions are unrealistic because they require a willingness to accept general commitments for situations which cannot be foreseen in detail and to carry them out under circumstances where the immediate national interest appears to dictate a different course. Thus, in the case of League sanctions against Italy, France was a reluctant participant because of her primary interest in having Italian support against Germany. Many members of the United Nations were reluctant to press sanctions against Communist China in 1950 and 1951 because of their greater concern at the time with the security of western Europe.

A more optimistic and positive view regarding sanctions is that while experience to date may not have been encouraging, a system of organized sanctions in support of law and order is the only alternative to anarchy. Scholars and writers who take this view—Quincy Wright and Myres McDougal are examples—argue that our experience with sanctions as applied to organized groups is not so discouraging as is often contended, that sanctions have been effective in deterring undesirable conduct by states, and that with a fuller appreciation of the extent of the coincidence of particular and general interests in public order, sanctions can be expected to become more effective.

### Problems and prospects

It is obvious that the organization and application of international sanctions in support of international order present difficulties that do not exist to the same degree in the case of sanctions in sup-

port of domestic order. With respect to international legal claims, states generally continue to rely upon good faith and reciprocity of interest in compliance, and upon retaliatory measures when these fail. It is primarily for the maintenance of peace and, to an increasing extent of late, for the implementation of certain human rights that organized sanctions are seriously considered. Much study has been given to the organization and application of collective sanctions to these ends, both by private scholars and by official groups.

A group of members of the Royal Institute of International Affairs made a study of international sanctions in the light of the League experience of 1935–1936 (1938). During the period when the United Nations was engaged in supporting collective measures in Korea, the General Assembly, by its Uniting for Peace Resolution of November 3, 1950, established the Collective Measures Committee to study methods which might be used to strengthen international peace and security. In its report, published in 1951, it made detailed recommendations for the organization and application of collective measures (United Nations . . . 1951).

The scope of the prohibition of the use or threat of force under the Charter, combined with the lack of any effective provision for the enforcement of legal rights, has led some scholars to take the view that unilateral use of force to secure respect for legal rights is permissible as a sanction consistent with "the Purposes of the United Nations" (Stone 1958, pp. 94–95). Others take the view that the Charter does not permit the individual use of force, without United Nations authorization, except as it can be justified as an exercise of the right of self-defense in case of an armed attack.

There is an extensive scholarly literature dealing particularly with the theory and legal aspects of international sanctions, but research and writing have thus far neglected the more practical aspects of the problem. While scholars have explored the legal, organizational, and administrative problems involved in the establishment and operation of a system of sanctions, and furthermore have analyzed the influence of the international political environment on a system of sanctions, relatively little attention has been given to the effects of sanctions upon the delinquent states as well as upon those states joining in their application. It is too readily assumed that the recalcitrant state can be coerced by material pressures into conforming to a desired mode of conduct or into ceasing an undesirable mode of conduct. We need to know more about the effect of sanctions upon the people of the state that is the object of sanctions, and the

processes by which that state, once its resistance is overcome, can be restored to good standing in the international community.

Furthermore, while the problem of the unequal effects of sanctions upon those states applying them or expected to apply them is recognized, more study needs to be made of the extent of these inequalities and of procedures by which burdens will be more equally shared. It is clear that reluctance to participate in the application of sanctions has in large measure been due to unequal burdens and risks that states have been asked to assume.

## SAPIR, EDWARD

- I. CONTRIBUTIONS TO CULTURAL ANTHROPOLOGY David G. Mandelbaum  
II. CONTRIBUTIONS TO LINGUISTICS Z. S. Harris

#### I

##### CONTRIBUTIONS TO CULTURAL ANTHROPOLOGY

Edward Sapir (1884-1939) was one of the founders of modern linguistic anthropology, a main contributor to the development of formal descriptive linguistics, a leading figure in cultural anthropology, and a chief stimulator of studies in the relations between personality and culture. His ideas continue to excite lively interest; his writings are widely read; his one book, *Language*, and a volume of his papers have continuously been reprinted. The range of his ideas is great. They are founded on an extraordinary breadth of knowledge, which Sapir used with incisive power of thought and subtlety of analysis. He wrote poetry, literary essays, and music as well as scholarly works; all his writings are characterized by an unusual felicity of style.

Sapir was born in Pomerania (Germany) and was five years old when his family emigrated to the United States. His intellectual gifts were recognized while he was a schoolboy in New York City. He was awarded scholarships to the Horace Mann School and then a Pulitzer fellowship to Columbia College, from which he was graduated in 1904. He went on to do a year of graduate work in Germanics at Columbia, and at that time his interest in language brought him into contact with Franz Boas. He quickly learned from Boas the great potentialities of the anthropological study of language, and from then on his principal work was in linguistic anthropology. [See the biography of Boas.]

In 1910 Sapir went to Ottawa as chief of the division of anthropology in the Geological Survey of Canada. His 15 years in that post gave him fine opportunities for field research and writing, but it was also a period of relative isolation from the main centers of anthropological work. He welcomed the invitation to join the department of anthropology at the University of Chicago, all the more because his wife had died after a long illness. He came to Chicago with his three children in 1925 and remained at the university for six years; his work and his influence flourished there. He was married again, to Jean McClenaghan, and they had two children. In 1931 he accepted a Sterling professorship at Yale and founded the department of anthropology there. His years at Yale were active and productive until he suffered a series of heart

attacks in 1937, which ended his life two years later.

Sapir's primary work was always in the study of language (his achievements in that field are discussed in the second section of this biography). His writings on other subjects, such as culture, society, and personality, were often done in response to a request for an article on a particular topic or as offshoots of his linguistic studies. Yet a good many of them have been major contributions which still command attention. These writings are of three main kinds—ethnological studies of American Indians, essays on general concepts, and papers on personality in culture and society.

**Ethnological studies.** Sapir's ethnological contributions appeared in steady succession from his earliest writings to some that were published posthumously. Many were brief studies of the kind that provide the necessary groundwork for more general formulations, as the account of Takelma religion, or of a Nootka puberty ceremony, or of Sarsi pottery. In some, a large body of data is summarized and underlying principles demonstrated. For example, in "The Social Organization of the West Coast Tribes" (1915) Sapir showed how the idea of social ranking pervaded many aspects of these societies—how the emphases on inherited privileges and on ritual insignia were linked to that prevailing idea. When Robert Lowie wrote an appraisal of Sapir's work long after Sapir's death, he noted that Sapir was one of the very best of ethnographers—able to immerse himself in the phenomena under scrutiny, plumb them to the depths, and present them deftly and incisively (*Letters From Edward Sapir to Robert H. Lowie*, p. 10).

Sapir's most substantial contribution to ethnological theory is his monograph of 1916, "Time Perspective in Aboriginal American Culture: A Study in Method." A main objective of field research among American Indians at that time was understanding the actual processes of culture change as against the presumed universal processes, which had been postulated by nineteenth-century evolutionists. In order to understand how American Indian cultures had actually changed, anthropologists had to reconstruct cultural histories. In this monograph Sapir surveyed the methods useful in such reconstructions; he particularly illuminated the use of inferential evidence, such as that from the study of cultural associations, geographic distributions, cultural strata, and from grammatical and lexical analyses. He presented the logical basis for evaluating different kinds of inferential evidence. The arguments are

closely reasoned; supporting evidence is compactly presented; broad concepts are tersely stated.

It is a work that requires close study, and generations of graduate students studied it closely because it was for many years one of the major theoretical pieces on American Indian anthropology. Some of these students found that a single paragraph or even a sentence could open fruitful leads for their own research. In recent years, the shift of anthropological attention to peoples in other parts of the world and the development of interest in other theoretical approaches have lessened the importance of this work, but it held a leading place for some forty years.

**General concepts.** Sapir's less technical, more general essays have had a wider audience; they have a way of including some ideas which appear, decades later, to be at the frontiers of thought. Thus, in "Culture, Genuine and Spurious" (1924), Sapir defined the anthropologist's characteristically objective view of a people's way of life and then went on to distinguish genuine and worthy cultures from spurious and morally shoddy ones. He valued those cultures that encourage harmonious and self-satisfying lives for the people who live by them, whatever the level of technical achievement and efficiency. He decried those life styles, as of some modern industrial and service workers, in which a person finds little relationship or reciprocal gratification among his various roles and pursuits. This thesis, although strange to anthropology, was true to the intellectual temper of the time. Sapir's special touch is found not only in the evidence he selected and the telling way in which he presented it, but even more in the intriguing ideas he mentioned, as it were, in passing. Thus, he commented on the nexus of self and society, on the place of art in a genuine culture, on the cultural pressures generated by political forces. Of this last matter he wrote, "Our national-political units are too small for peace, too large for safety" ([1924] 1949, p. 330). There is a good deal in this essay that belongs to the 1920s, but there is also a good deal that holds interest still.

Other essays clarify fundamental concepts and categories. In "The Meaning of Religion" (1928) Sapir took a subject which, in other hands, is often hackneyed; in his, the subject is treated freshly and lucidly, with proper anthropological objectivity and yet with sympathy. Here also he threw off a number of productive ideas, pointing out, for example, that a basic distinction among religions is exemplified by the contrast between Plains and Pueblo Indian practices. The two types tend to differ "according to whether they find the last court of appeal in mat-

ters religious, in the social act, or in the private emotional experience" ([1928] 1949, p. 350).

The article "Anthropology and Sociology" (1927a) appeared as a chapter in a book on the social sciences and their interrelations. In it Sapir was not at all concerned with separating the two domains or negotiating boundaries between them. He concentrated instead on the ideas that anthropology can contribute toward an understanding of people and behavior. He began by noting that a main error of earlier theorists lay in taking primitive people to be archaic, unchanging prototypes. Sapir expressed the view that has now become accepted, that "we are to be at least as much interested in the many points of accord between primitive and sophisticated types of social organization as in their sensational differences" ([1927a] 1949, p. 336).

These similarities, he continued, are not readily apparent from reconstructions of culture histories of American Indian tribes. It is rather from the "stupendous facts" about common human trends that sociologists will in the long run have most to learn from anthropology. The separate historical explanations are little more than a necessary clearing of the ground for a social interpretation; they are not to be mistaken for the interpretation itself. In his "Time Perspective" (1916) Sapir had provided a major theoretical foundation for the work of historical reconstruction, which then preoccupied most American ethnologists. In the article of 1927 he recognized the work he had done in 1916 as only a preliminary step toward the anthropologist's principal tasks.

Another development of Sapir's thought appears in several of the articles he wrote for the *Encyclopaedia of the Social Sciences*: an emphasis on the relation between individual and society, between personality and culture. This emphasis arose partly because of Sapir's humanist feeling that the proper study of man must include real men and partly because of his realization that formal, non-personalized formulations about people can be very misleading unless they are coupled with insights into the real experience and reactions of actual persons. In the article "Group" (1932a), for example, Sapir sketched the essential definition and dimensions of the concept in his clear, succinct way. He outlined three types of classification based on objective observation and three based on subjective engagement of the participant. He noted the bases for group formation and changes, then posed the fundamental question of the bonds that hold together the members of a group. The psychological basis of the group, he observed, must rest on the psychology of specific social relations. Loyal-

ties to an entire group do not mean that direct relationships between individual and individual have been completely transcended, but rather that the attributes of interpersonal experience have been transferred to the group as a whole. Thus the psychological realities of group participation can best be understood through studies of the actual kinds of understanding and expectation that grow up between two or more human beings when they are brought into significant contact.

**Culture and personality.** Sapir's interest in the interplay of culture and personality dated from the beginning of his anthropological studies. "I remember being rather shocked than pleased," he wrote in a paper of 1938, "when in my student days I came across such statements in J. O. Dorsey's 'Omaha Sociology' as 'Two Crows denies this'" ([1938] 1949, p. 569). The paper is devoted to an assessment of Two Crows' denial and of what the anthropologist should make of it. Sapir found conventional ethnographic statements inadequate because they were generalized formulas which said little or nothing about variation, conflict, denial, or emotion. Even as a student Sapir recognized that such generalized formulations might be necessary but could not be sufficient for a thorough understanding of behavior. So Dorsey was ahead of his age in recognizing that he was not dealing with an abstracted society or a set of specimens but with a number of human beings who could give themselves the privilege of differing from each other on matters that were, in the conventional anthropological definition, part of the official tribal culture.

Sapir was moved to point out the inadequacy of rigidly depersonalized studies in his response of 1917 to A. L. Kroeber's formulation of the concept of the superorganic. In "Do We Need a Superorganic?" he granted that few individuals, as individuals, make a marked impress on social movements, and yet it is always the individual who thinks and acts and dreams and revolts. The difference between social and individual data in behavior studies results from the observer's choice of what to select for systematic notice. Hence it is not valid to draw an abidingly sharp line between the two types of data, since "individual" reactions constantly spill over and give color to "social" reactions (1917, p. 442).

This insistence on the significance of the person appears recurrently in Sapir's writings on culture and society. His paper "Speech as a Personality Trait" (1927b) is one instance of this theme; other expressions of it came in a series of papers written in the last decade of his life.

In a paper of 1932 he restated the idea that

the true locus of culture is in the interactions of specific individuals and in the meanings which the participants abstract from these interactions ([1932b] 1949, p. 515). And in an article of 1938 he proposed a research procedure that has only lately been appreciated. Instead of arguing from a supposed objectivity of culture to the problem of individual variation, Sapir recommended that for certain kinds of analyses we should operate as though we knew nothing about culture but were interested in ascertaining what a set of human beings who are accustomed to live with each other actually think and do in their day-to-day relationships ([1938] 1949, p. 574). This simple discovery procedure, as it turned out, involves complex questions as to when and how it is to be used, but it can also lead to considerable advances in anthropological understanding.

As for the interpretation of a particular sequence of behavior as being either social or personal, Sapir's paper of 1934 on this matter shows that the duality of reference is an inevitable part of human experience as well as of the social scientist's method. When one is confronted with familiar circumstances and familiar people, interest is likely to be focused on the individual. With unfamiliar people or situations, in socially distant or casual relations, one's interest is more likely to center on cultural or social observations. Each type of interest "is necessary for the psychic preservation of the individual in an environment which experience makes increasingly complex and unassimilable on its own simple terms" ([1934] 1949, p. 591). Every person must use both frames of reference in his own conduct. In the study of man the anthropologist must also use both, but with explicit awareness of what he is doing, and he must be able to deploy each in ways best suited for analysis and explanation.

Sociology and anthropology, Sapir continued, are rooted in the social kind of reference, a kind which perhaps is characteristic of the child's earliest experience with the seemingly irresistible authority and knowledge of his parents. Psychiatry and social psychology proceed more from the personal kind of reference and from the necessity felt to assert oneself significantly. All these are "preliminary disciplines" and provide an invaluable first ordering of research.

But sooner or later their obscure opposition of spirit must be transcended for an objectivity which is not merely formal and non-evaluative but which boldly essays to bring every cultural pattern back to the living context from which it has been abstracted in the

first place and, in parallel fashion, to bring every fact of personality formation back to its social matrix. ([1934] 1949, p. 592)

For such purposes, the descriptions and classifications of abstracted culture patterns are no longer very relevant, useful as they are to clear the observational ground. The more anthropologists become concerned with interactional meanings and values rather than with segregated traits, Sapir commented, the more a culture seems to take on the characteristics of a personality organization, and the growth of culture is understood in the spirit of the development of a personality. Thus, such ethnological questions as that of clan membership may well become subsidiary to inquiries as to whether a father is in the habit of acting toward his son as an indulgent guide or as a disciplinarian. One result of taking this point of view is that the bizarre or exotic in alien cultures tends to be minimized, while the broad human base on which all culture has developed is revealed more clearly (*ibid.*, pp. 594-595). Anthropologists who appreciate that a culture is not given in a neat package to the child, but is gropingly discovered and assimilated by him, and who can see that a people change their culture with similar groping assimilation, will join with psychologists in phrasing more fruitful questions about culture and behavior ([1932b] 1949, p. 521; [1934] 1949, p. 597).

**Influence.** Sapir taught students of anthropology for only about a dozen years, but his influence on several generations of anthropologists and linguists has been considerable. Hearing him in lectures or discussions could be an exhilarating experience. He was not at all dramatic; his talk was low-keyed and anything but hortatory. But he could give his students glimpses of intellectual vistas the like of which they had neither seen before nor would soon forget.

He came to differ with his teacher in anthropology, Franz Boas, on a number of fundamental matters, but Boas always maintained a high respect for Sapir's work. Colleagues and friends of his own generation showed how much they owed to his work by the formal honors they gave him during his life and by the appreciations they wrote after his death at age 56. Parts of his correspondence with two of his friends, Robert H. Lowie and Ruth Benedict, have been published (Lowie & Sapir 1965; Benedict 1959, pp. 45-54, 158-197). These letters between friends contain private banter, trade gossip, and transient comment. But they also tell something of the day-to-day context of Sapir's

life and work—for example, at one period in Chicago he was teaching as much as fourteen hours a week—and they reflect something of both the warm charm and the occasional friction in his personal relations. The letters to Lowie show Sapir in the course of developing ethnological and linguistic ideas, sometimes surely and swiftly, sometimes haltingly and piecemeal. Those to Ruth Benedict show his sharp insight into the world of poets and poetry, a world seemingly very far removed from the technical universe which he discussed with Lowie but actually interwoven in his personality and his work.

In her account of Ruth Benedict's poetry, Margaret Mead has noted that "it was in the vivid, voluminous correspondence with Edward Sapir that her own poetic interest and capacity matured." And in another passage Margaret Mead mentions that among those who benefited most from Sapir's speculations about personality and culture were Ruth Benedict, John Dollard, and herself (Benedict 1959, pp. 90, 209). The memorial volume for him written by some of his students (*Language, Culture, and Personality* 1941) was reprinted in 1960. In the generation of the students of his students, there is not only quite lively interest in what Sapir had to say, but also a good many who are urging their students to read Sapir.

Sapir's death cut short a number of scholarly enterprises, among them the analysis of a large collection of American Indian ethnological data, extensive explorations in Indo-European linguistics, preliminary formulations of linguistic relationships on the largest scale, and extensive ethnological and linguistic notes in Semitics. Toward the end of his life he turned increasingly to Semitic studies. His father had been a cantor, and he had been raised in the strict tradition of Orthodox Judaism. Although he soon discarded what he felt to be the intolerable restrictions of orthodoxy, he retained his delight in the scholarship and spirit of Judaism. His strong commitment to human rights, opposing all invidious discrimination and oppression, appears in his writing, especially in articles done for general audiences. As the grave world events of the 1930s developed, he participated actively in the defense of these rights.

The weight of his scholarly influence is in linguistic anthropology, where the weight of his published contributions also lies. In American Indian ethnology his ideas on method and leads for further research have had notable effect. In the field of culture-personality studies he remains one of the principal pathfinders. For anthropology in gen-

eral he continues to be a heartening example of how much can be accomplished when a superb mind plays over a wide and richly yielding field.

### CONTRIBUTIONS TO LINGUISTICS

Sapir was, with Leonard Bloomfield, a founder of formal descriptive linguistics and the distributional method that characterizes it. He developed phonemic theory, the analysis of the sounds of a language according to the pattern of their distribution—that is, the sequence in which sounds occur and are systematized and perceived by the speakers of the language. Phonemic analysis thus recognizes language as behavior resulting from a process of selection.

This method of analysis classifies each part of an utterance (sound, morpheme, etc.) on the basis of its environment rather than on the basis of its meaning, phonetic properties, and so forth. The distributional method is important not only because it is self-contained but also because its universe and its terms of reference are so explicit that one can discover all sorts of hidden relations that are observable only as second-order disturbances in the overt distributional system: masked and combined phonemes, neutralized phonemic differences, zeroed morphemes, and the like. To be sure, Sapir did not always formulate aberrant phenomena in distributional terms; he sometimes used formulations drawn from biological processes. While this reduced the incisiveness and generality of the distributional theory he was developing, it did indicate some of the other systemic factors (factors of equilibrium, of dynamics, etc.) that may be required to understand the sources of aberrant phenomena or of the place these phenomena occupy in the descriptive system. These additional factors may even aid ultimately in understanding the source of the system itself. Thus Sapir might say that if, in a given language, a two-vowel sequence never occurs inside a morpheme and only rarely occurs when two morphemes adjoin each other in a word, the language will develop a "protective mechanism" to avoid the two-vowel sequence. Examples of such

mechanisms are the glottal stop and the French liaison *t*.

Distributional methods came to be widely used in the formulation of linguistic process. Phonemic phenomena were regarded as processes of change (for example, "suppletion," or the replacement of stems in certain word groups, e.g., in *am*, *is*, *be*) that are structural and thus related to the environment in which they occur. Sapir was also one of the originators of the concept of the morphophoneme. The morphophoneme classifies together all those phonemes that replace each other in the paradigm—that is, the different phonemic shapes that a word or morpheme has as it occurs in different morphemic environments. This concept was also based partly on the speaker's perception of phonemic replacement (Sapir 1933; Sapir & Swadesh 1939).

Sapir also did much work in historical and comparative linguistics, tracing the genetic relationships among languages. His interest in pattern and process led him to speak of configurational pressure as a source of change. By configurational pressure he meant that linguistic change (phonemic and morphemic) is influenced by relevant patterns inherent in the language itself. He suggested that configurational pressure is a factor in what he called drift, the process that occurs in a language whose speakers have separated and can no longer imitate ("borrow from") each other, but whose linguistic habits continue in some respects to change in the same way in the separated communities (e.g., Old Norse in Denmark and Iceland). Although this suggestion has not received sufficient study, it does accord with systematizations of linguistic change.

In historical linguistics Sapir is particularly noted for a series of intricate analyses of the earliest stages of Indo-European. He based his work partly on the difficult data from Tocharian and partly on the laryngeal hypothesis that reconstructed various laryngeal consonants lost in early Indo-European with consequent changes in neighboring vowels (1937a; 1937b; 1939). Related to this work were his investigations of the similarities and connections of Indo-European to Semitic and other Mediterranean languages. Sapir thought that Indo-European and Semitic might have descended from the same parent stock. Although it was impossible to establish this hypothesis by reconstructions using the accepted comparative method, he could point to many unexpected connections and to a great over-all structural similarity in the earliest stages of both Indo-European and Semitic.

Sapir worked with examples of structural simi-

larity in his famous attempt to group the extremely numerous and apparently unrelated families of North American Indian languages into six superfamilies (1929). Most of Sapir's linguistic work (like his ethnological studies) was with American Indians, and his mastery of the data and his analyses of the Indian languages were unequalled. He worked particularly in Navajo, Yana, Nootka, Tlingit, Sarsi, Kutchin, Chinook, Ingalik, Hupa, and Southern Paiute.

## SARTON, GEORGE

George Sarton, historian of science, was born in Ghent, Belgium, in 1884 and died in Cambridge, Massachusetts, in 1956. He married Eleanor Mabel Elwes, an English artist, in 1911; their daughter, May, who became a poet and novelist, was born in 1912.

As a youth Sarton wrote romantic poems and essays. At the University of Ghent he studied the natural sciences and mathematics, winning a medal for a chemical memoir in 1908 and com-pleting a doctoral dissertation on Newton's me-chanics in 1911.

He became increasingly interested in the history and philosophy of science and dedicated the rest

of his life to establishing the history of science as an independent discipline. In 1912 he founded *Isis*, a scholarly journal for this new field, and con-tinued to be its editor through 1952. After only five issues, publication was interrupted by World War I, but it was resumed in 1919. Meanwhile Sarton had fled Belgium and moved to the United States in 1915. As a research associate of the Car-negie Institution, from 1918 on, he used Harvard's Widener Library and offered a course in the history of science at Harvard, where he became a profes-sor in 1940. The History of Science Society was formed in the United States in 1924; it provided a professional organization for the new discipline and guaranteed the publication of *Isis*. *Isis* has pub-lished a continuous series of valuable critical bibli-ographies; the first 79 of these were prepared by Sarton himself. *Osiris* was founded in 1936 to ac-commodate studies that were too long for *Isis* but too short for separate publication.

When Sarton was invited, in 1916, to deliver the Lowell lectures, he chose Leonardo da Vinci as his subject. On this occasion he was struck with how little was known about ancient and medieval sci-ence leading up to Leonardo, and he decided that a comprehensive history needed to be written. In 1919 he recovered his notes and a good part of his library, which he had had to abandon in Belgium, and two years later he began to write his *Introduc-tion to the History of Science* (1927–1948). Ulti-mately, Sarton did not take this history beyond the fourteenth century; he realized how much time would be required to handle the fifteenth century on the same scale as the earlier centuries and pre-ferred to spend his remaining years on more lim-ited subjects; for example, he wrote *A Guide to the History of Science* (1952a), *The Appreciation of Ancient and Medieval Science During the Renais-sance* (1955), and *Six Wings: Men of Science in the Renaissance* (1957).

His aim in writing the history of science was not only to establish and define that field of study but also to show its importance for the philosophy of science and for any positive philosophy. Sarton called science "systematized positive knowledge," picturing it as a living, continually developing or-ganism. He maintained that science is the only cumulative and progressive human activity and that the study of the history of mankind must focus on the history of science; any tolerably complete history of civilization must devote considerable space to explaining scientific progress. He believed that the historian of science has a mission to de-fend the traditions of science, not because they differ essentially from those of other fields, but

because "they are all that makes life worth living, they are the nobility and the goodness of life" (1952a, p. 15).

For Sarton, science has grown "out of the minds and hearts of living men" (1954, p. 67), and its history is therefore often best written in terms of biography. He did not limit his account to the achievements of outstanding scientists, because he found that a number of smaller discoveries usually contributed to the gradual preparation of major ones. He warned that the history of science must not be confused with the history of scientific method, nor be approached from the economic point of view, which overemphasizes applications.

Influenced by Comte and Tannery, Sarton repeatedly emphasized that the history of science is the integration of the histories of the separate sciences, not their summation; it is itself a specialty built on a thorough understanding of the methods of science and of history; it covers ancient, medieval, and modern science; and it requires more than the leisure hours of capable scientists or of scholarly historians. The historian of science must be trained in science; indeed, he should be acquainted with all advancing knowledge, not just scientific and historical material. Moreover, Western science cannot be properly understood without an appreciation of the extent of the influence of Islam on Western civilization, and Sarton learned Arabic in order to comprehend this influence.

Sarton's history of science, an all-embracing picture of the impact of scientific progress on mankind and of man's environment on science, tells "not only of the spreading light but also of the contracting darkness" (1952a, p. 11). Sarton saw the history of science as a means of understanding science and making it live—creating a philosophy of science that would have continuing validity. He combated the tendency of scientific studies to supplant humanistic ones. He strove to "humanize" science, to reveal its integration with the other elements of our culture, and to instill in scientists some reverence of the past and some awareness of the relevance of the history of science for science as an ongoing activity. The history of science seemed to him the only possible bridge across a growing abyss.

Warm and subtly humorous, Sarton made friends throughout the world. He was tireless in his own work and expected similar patience and critical attitudes from others. Sometimes his genuine humility seemed like self-righteousness (e.g., [1931] 1956, p. 109). His lecture courses were popular, but he had few graduate students.

A new generation of historians of science, while appreciative of Sarton's pioneering service, is reassessing his aims and methods. Present-day emphasis is on the structure and development of scientific ideas rather than on the ideas themselves. Sarton has been described as naive about history (Williams 1960, p. 160) and insufficiently selective in his methods, too lost in pedantic minutiae to appreciate their relevance for the overall development. He has been accused by some of stressing the content of science at the expense of its integration into a complex whole. On the other hand, Sarton's interpretation of the history of science is alleged to be incompatible with the compartmentalism of modern science and to stress the cultural framework and the normative implications of science at the expense of its content (Grmek 1965, pp. 140–143). Grmek questioned whether one man can handle the history of science if it is interpreted as broadly as it was by Sarton, but he admitted that collaborative studies by teams of specialists have gained technical insight at the expense of the kind of synthesis that Sarton provided. Clearly, Sarton's critics are in disagreement. However, the monumental scholarly edifice he erected can become a basis for a revision of the historiography of science.

## SAUER, CARL O.

Carl O. Sauer, for more than thirty years chairman of the department of geography at the University of California, Berkeley, is one of the most influential figures in twentieth-century geography. The study of cultural geography, especially as it has developed in the United States, owes more to Sauer than to any other man. His concern for the quality of human life in its physical setting, for historical and ecological processes, and for the origins and dispersals of culture traits and complexes that have modified the cultural landscape is in the tradition of German geographical thought, of which Sauer has been a principal interpreter.

Born of German ancestry in Warrenton, Missouri, in 1889, he graduated from the local and now defunct Central Wesleyan College in 1908, having earlier studied for a time in a school in Württemberg, Germany, where he had family ties. His attachment to the rural and small-town ways of life and landscape of the Middle West of that period has played an important role in his teaching and writing, and he has frequently returned there for study and reflection.

Sauer next studied at the University of Chicago, where the first full-fledged graduate program in geography in the United States had recently been instituted. His PH.D. dissertation, *The Geography of the Ozark Highland of Missouri* (1920), was acclaimed as a model of regional cultural geography. In 1915 he was appointed to the staff of the new department of geology and geography at the University of Michigan, where in a period of seven years he advanced from the rank of instructor to that of full professor. His work in designing the

Michigan Land Economic Survey brought him national recognition. He left Ann Arbor in 1923, at the age of 33, to become chairman of the department of geography at Berkeley. Sauer retired from active teaching in 1957, except for occasional graduate seminars and guest lectureships, but his scholarly output has been undiminished.

Sauer also served the development of geography outside the university. He played an important role in the early development of land-use mapping in the United States and in the establishment of the U.S. Soil Conservation Service. For a time in the 1930s he was consultant to the President's Science Advisory Board. For many years he served as a member of the John Simon Guggenheim Memorial Foundation selection committee, in which capacity he had a unique opportunity to observe and influence a wide range of American scholarship. He has received honorary degrees from Heidelberg University, Syracuse University, and the University of California and medals from the American Geographical Society, the Berlin Geographical Society, and the Swedish Society for Anthropology and Geography.

Soon after Sauer came to California, he and many of his students turned their attention to northern Mexico, especially to the historical geography of the settlement of the dry northwestern part. Later he was to concern himself increasingly with tropical Mexico and Central America and, finally, with the Caribbean. Latin America was thus the strategic site for his observation of the interaction between the simpler, peasant cultures and the sustaining earth. Here, where the mark of the past is so deeply imprinted on the land, he found an especially congenial atmosphere for the study of the interplay between habitat and habitant. His careful reconstructions of past Latin American landscapes and economies, based on a combination of archival work and detailed field inspection, are models of historical geography. *The Early Spanish Main* (1966), an analysis of the Spanish conquest on the islands of the Caribbean and its margins, is their capstone. Several of his publications on Latin American subjects appeared in the University of California monograph series *Ibero-Americana*, which he founded in 1932 with A. L. Kroeber.

Sauer's outspoken rejection of environmental "influences" as the focus of geographical inquiry, enunciated in his *Morphology of Landscape* (1925), was a critical turning point in the development of American academic geography. Instead of the deterministic view that had largely dominated Ameri-

can geography since the turn of the century, he advocated geographical inquiry into such themes as the man-modified landscape and the origin, spread, limits, and alteration of the elements of that landscape. Holding that all geography is essentially historical, he systematically used any kind of data pertaining to human settlement and activity, and he often found archeological evidence fully as pertinent as written documents. For him the kitchen midden, the colonial archive, the relict plant community or soil profile, and the wisdom of the countryman at work on his hillside garden patch provided information equally relevant to the problems of cultural geography.

A recurring theme in Sauer's work is the tremendous importance and antiquity of the domestication of plants and animals. In *Agricultural Origins and Dispersals* (1952a), he summarized his efforts to locate the principal hearths of domestication and the subsequent routes and extent of dispersal. Using archeological and ethnographic evidence, Sauer argued that the origins of cultivation must have been in the woodlands rather than in riverine valleys of the world. He made a basic distinction between the agricultural complexes of monsoon Asia and northwestern South America, which are largely dependent on vegetative reproduction by slips and cuttings, and the seed cultures of southwest Asia and of Mexico and Central America. Sauer hypothesized that the earliest form of plant selection involved asexual plant propagation and that it was probably first practiced by the sedentary fishing peoples living around the shallow seas of southeast Asia. The early domestic animals of these peoples were household animals such as the dog, pig, and chicken. Sauer accepted the view that plant selection by seed reproduction came later, and he was influenced by N. I. Vavilov in pointing to China, India, and Ethiopia as Old World centers of seed domestication. He associated herd animals with cereal cultivation and accepted Eduard Hahn's theory of a mixed economy in which milking of animals was a culture trait integrally involved in the process and purpose of their domestication, probably for noneconomic ends. His research along these lines has especially attracted the attention of anthropologists and archeologists. Many of his speculations regarding the antiquity of man in the New World, Pleistocene ecology, and the relation of changing sea levels and shore configurations to human occupation sites continue to stimulate new research.

Sauer has insisted on the close links of cultural geography with both biology and the earth sciences. He sees man as the ecologic dominant in nature,

intervening more and more decisively to change the balance and nature of organic life. He has, for example, insisted that the problems of increasing world-wide desiccation are caused by agricultural and grazing practices and not by "climate deterioration." He has repeatedly written about the historical processes of biotic destruction and soil depletion as reflections of changing technology and changing attitudes about the earth. Another theme in his writings has been the role of fire, especially of fires set by man, in the modification of the vegetative covering of the earth and the establishment of grasslands. He was the principal organizer of an international symposium held at Princeton in 1955 that focused on "Man's Role in Changing the Face of the Earth" (1956a).

Sauer has viewed with misgivings the growing emphasis of some of his colleagues on techniques and tools of analysis that produce quantitative results: he has insisted that the qualities of both human society and the man-made landscape are often other than those that permit quantitative processing (1952b). Leighly has observed that to Sauer the investigation of human beings and their behavior by mechanical processes of organization and computation is as repugnant as the environmental determinism he rejected years earlier (see the introduction by Leighly, to Sauer's *Land and Life*, p. 6). Human geography, Sauer has said, exists because of the diversification that exists in human ways, and no approach to its questions is more rewarding than that of comparative culture history, soundly based on ecological and geographical principles and concepts.

#### SAUSSURE, FERDINAND DE

Ferdinand de Saussure (1857-1913), Swiss linguist, was the chief forerunner of structural linguistics. He was born in Geneva, where he received his secondary and university education. He was awarded his doctorate at Leipzig in 1880, taught at the École Pratique des Hautes Études in Paris from 1881 to 1891, and taught subsequently at Geneva for the remainder of his career.

De Saussure's fame rests almost exclusively on two works—his earliest, the *Mémoire sur le système primitif des voyelles dans les langues indo-européennes* (1879), and the posthumously published *Cours de linguistique générale* (1916). The *Mémoire* is a brilliant tour de force, whose basic method foreshadows the fundamental structuralist notion of language as an organized system, the

central doctrine of de Saussure's mature thought. [See LINGUISTICS, article on THE FIELD.]

In the *Mémoire* it is boldly hypothesized that certain apparently divergent aspects of the Indo-European system of vowel alternations (the so-called ablaut system, which still survives in English in such vowel changes as the present *sing*, the preterite *sang*, the past participle *sung*) can be explained in accordance with the dominant regularities, if one assumes that certain sounds had formerly existed and produced certain effects before being lost. While this theory of lost sounds, subsequently called laryngeals, was admired in de Saussure's lifetime, the absence of any direct evidence for these sounds prevented its acceptance by scholars. After de Saussure's death the main points of his doctrine regarding the Indo-European vowels received confirmation when a newly discovered Indo-European language, cuneiform Hittite, was shown to have an actual laryngeal consonant (h) in almost all the instances that one would expect to find it on the basis of de Saussure's theory. In one variant or another, the laryngeal theory is now accepted by all Indo-European scholars.

A far wider influence was exercised by the *Cours*. This work is based on students' notebooks of the three courses in general linguistics given by de Saussure at the University of Geneva in 1907, 1908-1909, and 1910-1911. Two of de Saussure's leading disciples, Charles Bally and Albert Sechehaye, utilized these as their chief source in putting together the *Cours*. Given these circumstances of the book's composition, it is not surprising that an extensive exegetical literature has arisen concerning the true nature of de Saussure's doctrine. Godel (1957) published a considerable number of résumés and direct quotations from the notebooks and other unpublished sources, e.g., de Saussure's class notes and letters. It is quite likely that in some instances "fruitful misunderstandings" of de Saussure's ideas have exerted an influence on the development of European linguistic theory.

**Language as signs.** Language is a system of signs and as such forms the central part of a discipline—semiology—which takes the general study of signs as its subject matter. De Saussure thus anticipated the concept of general semiotics, found in the work of Charles Morris and others [see SEMANTICS AND SEMIOTICS]. The sign has two indissoluble aspects, likened to the two sides of the same paper—the signifier (*signifiant*) and the signified (*signifié*). De Saussure felt the need for the double terminology because of the ambiguity of the word "sign" in common usage, which refers

both to the relation (between a sign and what it designates) and to the physical sign vehicle. The signifier and the signified are, in thoroughgoing mentalistic fashion, the acoustic image and the concept respectively, not the physical sound and the thing meant. The relation between signifier and signified is arbitrary in the sense that any signifier can, in principle, be connected with any signified. Both of these elements are, abstracted from their functioning in signs, unstructured. Language is thus pure form.

Although arbitrary in the sense described above, the sign relation in any particular case is a historically imposed one about which the individual has no choice. It is a social fact that in a given community a particular sequence of sounds is connected with a particular concept. Simply because it is arbitrary, there is no reason to change it once established. One can argue the relative merits of monogamy or polygamy, but there is no rational basis for choosing between *boeuf* and *Ochse* as designations for "ox." Because language is arbitrary and because there is no social awareness of its true nature, it is never subject to radical change.

From the formal nature of the components of the linguistic sign further important conclusions follow. Thus, in the case of the signifier, it is not the particular physical nature of the sound that counts but merely the fact that one sound is distinct from another. A favorite Saussurean simile likens language to a chess game. If the knight is replaced by a different kind of physical object it makes no difference to the game as long as the object is distinct from the other pieces. But if the rules for moving the knight are modified, then the system of chess has been modified in its very nature. This distinction is one aspect of a central Saussurean dichotomy, that between language (*langue*) and speech (*parole*). Phonetics in its physical aspect belongs to the latter. Likewise in grammar, we have a network of two types of relations, the syntagmatic, the relation between elements which actually occur together in the chain of speech—e.g., a verb and its object—and the paradigmatic, the relation of a present element to one which is not there but has the potentiality of appearance in place of the one chosen. Thus, in the sentence "Black is a color," "white" is a paradigmatic associate of "black," while "is a" constitutes a syntagmatic relation.

The grammar of a language (*langue*) is the set of these two types of relations: it is a social product, never perfect in the individual but only in the mass of speakers (*masse parlante*). The way individuals actually construct sentences by using

*langue* constitutes *parole*. Within *langue* it is the position within the system that counts, not the physical realization. Thus a grammatical category may even be signaled by nothing (*zéro*), provided it has a particular place in a network of relations, e.g., the absence of an ending in the genitive plural of feminine nouns in Czech such as *žen* ("of women") is significant when it is opposed to the nominative plural, *ženy*. To be is to be related.

**Synchronic and diachronic study of language.** Another dichotomy of fundamental importance in de Saussure's thought is that between the synchronic study of language as a state and the diachronic study of language as change through time [see LINGUISTICS, article on HISTORICAL LINGUISTICS]. These now current terms are terminological inventions of de Saussure. The insistence on the separation of synchronic and diachronic and the emphasis on synchronic states, not only as worthy autonomous subjects for investigation but even as having a certain priority, were perhaps de Saussure's most revolutionary ideas. Linguistics in its recognizably modern form arose in the early nineteenth century as a historical discipline, and de Saussure was the first to state clearly the viewpoint of modern structuralism—that language studied in a single time plane constitutes a systematic set of relations that can be studied without reference to the historic process by which these have come to be what they are. Thus, to revert to de Saussure's figure of the chess game, the man who has seen the entire game up to a particular point has no advantage over the newly arrived bystander in understanding the existing position.

In spite of differences in detail, structuralism in linguistics is fundamentally allied with functionalism in social science generally and is part of the same intellectual movement. In the case of de Saussure, his notion of *langue*, a social phenomenon imposed on the individual, brings him closest to the social functionalism of Durkheim. Although Durkheim cited language as an ideal example of a social institution, there is apparently no evidence of any direct influence of either man on the other.

The posthumous influence of de Saussure's ideas in general linguistics was enormous, particularly on the Continent. His work was most directly continued by the so-called Geneva school, which included among its leading figures Albert Sechehaye, Charles Bally, Robert Godel, and Henri Frei and which sponsored the journal *Cahiers Ferdinand de Saussure* (from 1941 to the present). The glossematic approach developed by the Danish linguist Louis Hjelmsler was founded on Saussurean con-

cepts. De Saussure exercised a more diffuse influence on the chief European structuralist school, that of Prague, by which he was looked upon as a leading pioneer of structuralism in linguistics.

### SAVIGNY, FRIEDRICH CARL VON

Friedrich Carl von Savigny (1779-1861) was the founder of the older, romantic branch of the German historical school of law. He was born in Frankfurt am Main of an ancient and wealthy noble family from Lorraine, and his selection of an academic career was unusual for a member of his class. He began that career at the University of Marburg in 1800, teaching Roman law, and became professor of Roman law at Landshut in 1808. Two years later, at the suggestion of Wilhelm von Humboldt, he was appointed professor at the newly founded University of Berlin, where for three decades he had a most successful and influential career in legal teaching and research. From 1842 until the German revolution of 1848 he was Prussian minister for the revision of legislation.

In the academic year 1802/1803, Savigny gave a lecture on legal methodology at Marburg (see *Juristische Methodenlehre*), which shows him still poised between rationalistic and historical jurisprudence. (His student Jacob Grimm recorded this lecture.) However, the lecture contains some of the basic principles of his later doctrine, for example, that jurisprudence must be empirical and that it should be a synthesis of historical and systematic treatments of the law. He first applied these early

theories in *Das Recht des Besitzes* (see 1803), a treatise that immediately established his reputation as one of the leading professors of civil law. What contemporary legal scholars saw as the particular significance of the treatise was the way Savigny took from the sources of ancient Roman law the leading principles of the law of possession, demonstrating the superiority of the Roman principles over the modifications that this law had undergone in Continental jurisprudence since the Middle Ages.

Savigny's famous pamphlet *Vom Beruf unserer Zeit für Gesetzgebung und Rechtswissenschaft* (1814) was published as an argument against the popular demand for the codification of German civil law on the model of the French and the Austrian codes. The pamphlet established the doctrine and program of the early historical school of law. In this pamphlet, as well as in his introductory essay (1815) to the first volume of the *Zeitschrift für geschichtliche Rechtswissenschaft*, founded as the organ of the school in 1815, Savigny outlined a new theory of the creation of law, culminating in a strictly genetic conception and analysis of law. Taking off from the ideas of Montesquieu, Burke, and Justus Möser, he asserted that positive law is not a product of reason. From its true basis, the common beliefs of a particular nation, it develops in a continuous, "organic" process as do a nation's language and customs; it is the result of silent, anonymous, and irrational forces, of an implicit consensus, not of an intentional creative effort. Law is, therefore, of the same nature as custom; it is determined by the whole past of the nation and by its peculiar character (what was later called the *Volksgeist*), and it cannot be changed arbitrarily by legislation. Instead, Savigny advocated the reform of jurisprudence by means of historical research, holding that a strictly genetic study is the only way to conceive and develop contemporary positive law.

While some of Savigny's contemporaries (Thibaut, P. J. A. von Feuerbach, Gönner, and especially Hegel and his school) rejected his doctrine, the historical school of jurisprudence dominated German universities for nearly half a century. Its program of historical research, though neither wholly nor rigorously fulfilled, made the history of law a scientific discipline, by basing it on the idea of evolution. Savigny's own chief contribution in this field was his *Geschichte des römischen Rechts im Mittelalter* (1815-1831), which deals with the history of the sources, the literature, and the teaching of Roman law from the fifth through the fifteenth centuries. It initiated the modern study of medieval jurisprudence and has served ever

since, corrected in many respects but unequalled, as the standard work on the history of medieval jurisprudence in Europe. Savigny also wrote a number of historical monographs, mainly on ancient Roman law (collected in his *Vermischte Schriften*).

In the field of legal dogmatics, Savigny's doctrine re-created, by reviving the study of ancient Roman law, a common field of legal study in the individual German states—the "modern Roman law," or Pandects. His most important dogmatic works, *System des heutigen römischen Rechts* (1840–1849) and *Das Obligationenrecht als Theil des heutigen römischen Rechts* (1851–1853), show that the theories that he had put forward in 1814 and 1815 about the nature of law had not produced a radical change even in his own legal dogmatics. His early theories had been provoked by his reaction, influenced by romanticism, against the natural law theories of the French Revolution and of liberalism generally. Later, however, he not only retained the fundamental doctrines of the rationalist jurisprudence of the eighteenth century in his dogmatic teaching but actually made these doctrines the backbone of his legal system. Both of Savigny's works are based on fundamental notions of German natural law theory as well as on Kant's legal philosophy. Within the framework of these categories, Savigny transcended Roman law in many respects, adapting it to modern requirements or developing new solutions, many of which have become influential in German and other legal science; for example, his doctrines of contract and corporation, and particularly his system of private international law—which, like the systems of Story and Mancini, counts among the classic theories in this branch of law.

See CONSUMPTION FUNCTION; INTEREST; INVESTMENT.

## SAY, JEAN BAPTISTE

Jean Baptiste Say (1767–1832) was born in Lyons of a cultivated Protestant merchant family. After a sound education and a two-year stay in England, he joined an insurance company. Say was an enthusiastic supporter of the ideas of the French Revolution and took part as a volunteer in the military campaign of 1792. Bookish and inclined to philosophy, in 1793 he joined the editorial board of a new magazine entitled *La décade philosophique littéraire et politique, par une société de républicains*, which took as its motto "Enlightenment and morality are as much needed for preserving the Republic as courage was needed for winning it." He soon became the editor-in-chief of the journal, which announced that its aim was "to keep the public informed on everything new concerning literature, science, agriculture, and the arts."

In 1799 Say was appointed a member of the Tribunal, under the Consulate. He took part in a competition arranged by the Institut de France on the subject "By what means and what institutions can morality be established in a people?" His contribution, "Olbie: Ou, essai sur les moyens de réformer les mœurs d'une nation," gave promise of his gifts as a moralist and economist. Following up his thesis that "the first book on morality for the Olbians should be a good Treatise on Political Economy" (*Oeuvres diverses*, p. 593), he set about composing such a work, inspired to a great extent by the ideas expounded by Adam Smith in his celebrated *Inquiry Into the Nature and Causes of the Wealth of Nations*, with which Say had become acquainted as early as 1789. Say's book appeared in 1803 and soon had considerable success.

In the meantime, Say's disapproval of the Napoleonic regime led to his dismissal from the Tribunal. He moved to a small town in northern France, Auchy-les-Hesdin, to set up a cotton-spinning plant. He stayed there seven years before he sold out in 1813 and returned to Paris. The fall of the empire and the return of the Bourbons permitted him to resume intellectual activity aimed at the general public. In 1815 he began to teach at the Athénée what was probably the first public course of political economy ever given in France, and in the same year he published his *Catéchisme d'économie politique*. Two years later the government established a chair of industrial economy for him (the term political economy still frightened people) at the Conservatoire des Arts et Métiers. Finally, in 1830, the aged master did become professor of political economy at the Collège de France, in the first chair of its kind to be established. Meanwhile, he had

published his *Cours complet d'économie politique pratique* (1828–1829) in six volumes, a work, as the long subtitle indicates, "designed to teach statesmen, landowners and capitalists, men of learning, agriculturalists, manufacturers, businessmen, and in general all citizens, about political economy."

Although it has been alleged that Say was a mere expositor and popularizer of Adam Smith's ideas, he did more than merely transmit these ideas. He did, of course, present the ideas that he borrowed from Smith with typical French order and clarity, and he justly complained of obscurity and confusion in Smith's own statements in *The Wealth of Nations*. Say wanted to produce what he described as "a work in which sound observations were reduced to general principles that could be accepted by any judicious man; in which those observations and principles were so completed and coordinated as to reinforce one another, so that they could fruitfully be studied at any time and in any place" (1803, p. xlviii in 1860 English edition). And this was not merely an interpretative work: at important points Say showed originality, and he undoubtedly contributed to advancing the science of economics.

**Philosophical position.** In his basic philosophy, Say was strongly influenced by the ideological ambience of his time. Like many of his contemporaries, he was at once deist, liberal, and rationalist. In the realm of scientific and doctrinal convictions, however, he showed little toleration but instead a dogmatism that may have been related to his authoritarian nature. This is one of several ways in which he differed sharply from Adam Smith: he was never touched by doubt. As a disciple of the Encyclopedists, he was an intransigent scientist, even a passionate one, and convinced of the predominant influence of economic phenomena in the life of the whole society. On this point, as in the case of the preponderant role of industrial activity in production as a whole, it may be possible to establish a connection between Say's ideas and certain theories of Karl Marx, and in any event, with those of Saint-Simon and the Saint-Simonians.

His belief in economics as a science led Say to try to reconcile his naturalism and his rationalism. He was able to do so because he conceived of the laws of nature as necessarily rational (or providential); in this respect, he was adopting a point of view the physiocrats had developed a half century earlier. But it is noteworthy that Say went on to establish similarities between the science of economics and *physiology*, transposing the latter from the individual to the social level and preferring a

biological model of the economy to a purely mechanical one. He was later to be followed on the same track by Alfred Marshall, the great English economist. It should be pointed out, however, that Say's method was never made rigorously explicit. While asserting the sovereignty of facts in scientific matters, he nonetheless interpreted them according to the results that he intended to reach. Thus, he appeared as an "ideologue" to some of his contemporaries.

**Relationship to Adam Smith.** Say deeply admired the work of Adam Smith. Of *The Wealth of Nations* he said, "Whenever the *Inquiry Into the Wealth of Nations* is perused with the attention it so well merits, it will be perceived that until the epoch of its publication the science of political economy did not exist" (1803, p. xxxviii in 1860 English edition). But Say was not content merely to repeat or rethink the ideas of his master. He filtered them, clarified them, and at several points went beyond them. He made a more systematic critique of physiocratic ideas, based on an expansion of the concept of productivity and the inclusion of immaterial products among the positive results of economic activity. Say gave greater depth to value theory by introducing the notions of need and utility. As a true precursor of the marginalist school, he noted that the needs of men may be classified according to their urgency in scales of preference, that they give rise to utility, which in turn determines demand. Demand then interacts with supply, which in turn is determined by the cost of production. For Say, however, in contrast to Ricardo, for example, utility is the stronger determining factor in prices; the cost of production enters only as a kind of restrictive condition. There too Say appears to have anticipated Alfred Marshall's well-known theory. It is of interest to see that Say realized perfectly that the explanation of the phenomena of value and price is not to be sought in terms of unilateral causal relationships but in terms of the concept of interdependence.

Even more than Adam Smith, Say strongly emphasized that the role of science is primarily one of observation and explanation. Where Smith, following the physiocrats, came forward as a physician for society, Say aimed exclusively at being a naturalist. His *Traité* professes to be a "simple exposition" of a body of exact knowledge, applicable under all circumstances.

Although agriculture still had a predominant position for Smith, it no longer did for Say. To be sure, the half-century separating their work witnessed the entire industrial revolution in Britain, and in France its beginning. Say was in a position

to observe its first manifestations, in the seven years that he devoted to business. Thus he made industry and even commerce as important as agriculture in the total productive activity of society.

**Major contributions.** Say appreciated the importance of the *entrepreneur* in economic life, a role Smith had neglected to define and which has remained, since Say's time, a permanent feature of economic analysis. This essential actor has functions that are quite distinct from those of the capitalist strictly so called (British authors confused these two conceptions). The entrepreneur, whether he be an industrialist, businessman, or farmer, has a truly strategic position in economic life, in that he is par excellence the intermediary between landowners, capitalists, workers, and consumers. He is also pictured as performing a truly creative function as the organizer responsible for production, striving unceasingly to improve it, especially in the industrial sector. Over a century later, Schumpeter was to take up and perfect this dynamic conception of the role of the true entrepreneur, the creator of new combinations (innovations).

Say's development of the theory of the distribution of the social product, deduced from the previous analysis, was a marked advance over current theories. Say coordinated this theory precisely and harmoniously with the theories of exchange and production. The entrepreneur, a buyer of productive services at known prices (the services of men, capital, and lands) and a seller of products at uncertain prices, is thus seen as assuming a set of fundamental functions, as presiding in a way over activity that is both production and distribution. His specific share is the profit, a share that is described as essential, residual, and precarious. This brings us to the very threshold of Walras's grand conception of economic equilibrium.

Another of Say's highly original contributions to economic analysis is his famous *law of markets*, which undoubtedly did more to make its author celebrated than all the rest of his work. This law (cf. Schumpeter in *History of Economic Analysis* 1954, pp. 615-626) may be interpreted in many different ways. We know its very simple, almost lapidary content: "Products are exchanged for products." This may be taken as meaning that the role of money in the economy is, after all, secondary (the conception of the "monetary veil"). But one may also infer that everyone taking part in an exchange is interested in the prosperity of his partner, whether it be an individual or a nation, a thesis that goes counter to the mercantilist conception that "one gains only what the other loses." Finally, the law may imply a theory of crises, based

on rejection of the concepts of general overproduction and underconsumption and the assertion of the essentially transitory and limited nature of these imbalances. The remedy is therefore not the limiting of production but its expansion. "Produce, produce, that is the whole thing!" Say concluded, in his *Cours complet*, that although "there is an excess in certain products, there is a shortage in others."

**Importance and influence.** All in all, it would appear that Say's work, without bearing the marks of really great genius, does give its author an eminent place in the development of economic thought. Say was not entirely an innovator, even in fields where he was not following Adam Smith and did show real originality: on many points he links up to a tradition solidly rooted in France. As Schumpeter remarked judiciously (1954, p. 492): "Say's work is the most important of the links in the chain that leads from Cantillon and Turgot to Walras."

He opened up new paths, but later authors followed them with more success than he. This was the case with the members of the marginalist school—Carl Menger, Stanley Jevons, and especially Léon Walras—who were able to employ the notion of utility in a much more precise and scientifically valid manner than their common precursor, Say. (Walras tended to minimize his debt to Say, but it was nevertheless important.) Again, the fine effort at synthesis made by Alfred Marshall and the neoclassical school is not entirely untouched by the teachings of Say. His influence can be traced beyond the general equilibrium school to such essentially modern authors as Schumpeter.

It is true that in the eyes of many of our contemporaries Say is seen primarily as the author of the law of markets, one of the favorite butts of Keynesian and Neo-Keynesian criticism, and this "law," interpreted and misinterpreted as it has been, may remain his chief title to fame. But perhaps he will be remembered for his power to build on established intellectual traditions and to stimulate other thinkers: there lay his true merit, which only time will confirm.

### SCALE, ECONOMIES OF

See ECONOMIES OF SCALE.

### SCALES OF MEASUREMENT

See PSYCHOMETRICS; STATISTICS, DESCRIPTIVE; SCALING.

## SCALING

Measurement of a property involves assignment of numbers to objects as a way of representing that property. The process thus includes both a formal, logical system, e.g., the real number system, and an empirical system, the set of instances of the property.

**Scale types.** An important aspect of measurement is the correspondence between some of the characteristics of the number system involved and some of the relations between instances of the property. The particular set of characteristics of the formal number system that is used determines the *type of scale* that is obtained. Scale types can most easily be described by the type of transformation that can be applied to a given scale without changing the numerical interpretation of the basic empirical relations. Although there is no limit to the number of scale types that might be devised, only a relatively small number have been found useful. Some of the more important scale types are described here.

In ordinal scales the only relevant property of numbers is their *order*. Numbers are assigned to

objects so that the order of the numbers corresponds to the order of the objects with respect to the property of interest. Any transformation of a given numerical assignment that preserves order, i.e., any *monotonic* transformation, would serve as well. An ordinal scale is therefore said to be determined up to a monotonic transformation.

*Fixed-origin ordinal* scales are rarely discussed, but are of some empirical importance in the fields of social psychology and personality, where bipolar attributes are not uncommon. Of relevance in such scales is the fact that numbers have a unique origin. Numbers are assigned not only so that their order corresponds to the order of the objects but also so that the origin of the numerical series corresponds to an empirically meaningful origin or zero point of the property. Any monotonic transformation that does not change the origin leaves the numerical interpretation of the basic relations unchanged.

In *interval* scales, in addition to order, differences between the numbers correspond, in some generalized sense, to the distances or differences between the instances of the property. Interval scales are thus determined up to a linear transformation of the form

$$y = ax + b,$$

where  $a$  is any positive number and  $b$  is any number whatsoever.

*Log interval* scales are closely related to the interval scale. In the interval scale, numerical differences correspond to empirical differences; in the log interval scale, numerical ratios correspond to empirical ratios. The transformation characterizing the log interval scale is given by

$$y = ax^b,$$

where  $a$  and  $b$  are positive.

*Ratio* scales can be described either as those in which the order, the differences, and the ratios of the assigned numbers correspond to the order, differences, and ratios of instances of the property or as those in which order, differences, and origin all receive numerical interpretation. For either description, the ratio scale is determined up to a linear transformation of the form  $y = ax$ , where  $a$  is positive.

*Difference* scales and *ratio* scales are related in a way similar to the way that interval and log interval scales are related; in each case one scale is equivalent to the logarithm of the other. In the difference scale, the procedures used to assign numbers serve to fix the order, the differences between numbers, and the unit of measurement. The char-

acterizing transformation is  $y = x + a$ . [For a more extensive discussion of scale types, see *PSYCHOMETRICS; STATISTICS, DESCRIPTIVE*; see also Suppes & Zinnes 1963.]

The concept of scale type is important because the type of scale on which a property is measured restricts the kinds of information that can be obtained in an experiment. The scale type therefore limits the kinds of meaningful questions that can be asked regarding the property. Consider the following three questions:

*Do high-scoring subjects increase in ability more than low-scoring subjects (after some specified treatment)?* If the ability is measured on a scale that contains only ordinal information, and if both low and high scorers increase in ability with no overlap in distribution, then the question cannot be answered. The question deals with the relative magnitude of differences (or perhaps ratios), and in a purely ordinal scale the relative magnitude of numerical differences or ratios is meaningless.

*Is amount of aggression directly proportional to degree of frustration (in some specified situation)?* Let  $A$  denote amount of aggression and  $F$  the degree of frustration. The question then concerns the form of the equation that relates  $A$  to  $F$ , that is, one asks whether these two variables are functionally related by an equation of the form  $A = kF$ , where  $k$  is some positive constant. Clearly, an affirmative answer cannot be given unless both  $A$  and  $F$  are measured on ratio scales.

*Do college sophomores differ more widely in their attitude toward civil rights than in their attitude toward the Asian policy of the United States?* Questions such as this require a scale type ordinarily ignored in physical measurement. Consider the formally equivalent question "Does this set of containers differ more widely in their volume than in their weight?" The question, which does not seem particularly unreasonable in the attitude context, now appears absurd: a difference of  $x$  cubic inches is neither more nor less nor equal to a difference of  $y$  pounds. The two differences are simply not comparable. However, volume and weight are measured on ratio scales. If they, or the two attitude variables, were measured on difference scales, then a basis for the comparison would exist.

*Kinds of measurement.* So far, scale type has been treated as though it were an inherent part of a given numerical assignment. In one sense, this is correct; each scaling procedure includes a set of rules governing assignment of numbers to instances of the property. The rules limit to varying extents and in varying ways the freedom of the investigator to decide which numbers to assign to the instances

of the property. The characterization of scale type by admissible transformations is simply a compact way of stating the particular restrictions imposed.

But scaling procedures also differ markedly in the quality of information the numbers represent. At one extreme are measurement procedures that rely almost entirely on definition or assumption. An experimenter might simply *define* the attitude of a subject to be equal to the number of favorable responses he gives to a specified collection of items. Such *measurement by fiat* has been both useful and common throughout the behavioral sciences. The type of scale resulting from such a procedure is simply a matter of *definition* or *assumption*. Although these procedures determine a unique number to be assigned to a given subject, the experimenter may have reasons for wanting to attribute meaning only to the ordinal property of the numerical assignment. Or he may want to attribute meaning to both ordinal and interval properties, thus obtaining an interval scale. Suitable modifications of the definition could therefore result in any of the scale types already described. Obviously, such modifications do not change the empirical basis of the numerical assignment, which, in the present instance, is simply the number of favorable responses to the particular set of items.

The usefulness of such defined scales depends heavily on the experience and intuition of the investigator. The scales tend to be exceedingly special. Different investigators, when defining scales in this way for the same attribute, would ordinarily select different, or at best only partially overlapping, sets of items. Because favorable responses depend as much on the nature of the items as on the attitude of the subject, the value assigned to a given subject would clearly be expected to differ from one scale to another. While the scales might be ratio scales by definition, it is unlikely that they would differ from each other only in unit of measurement. The procedures themselves provide no basis for choosing among the many scales of a given attribute that might be defined in this way. Hence, confidence in any one cannot be expected to be great.

A somewhat different procedure for obtaining scale properties by definition relies on assumptions made about the distribution of subjects. The investigator might stipulate, for example, that the number of favorable responses to his set of items only serves to order the subjects on the attribute. But he then might go on to assume that his population of subjects is distributed in some specified way on the attribute (ordinarily, the assumption of a normal distribution is made, but other distributions could serve as well). Knowledge of order and

of the properties of the assumed distribution enables the investigator to increase the level of the scale from ordinal to interval or perhaps even to ratio. But again, the meaning of the interval or ratio properties of the scale is derived only from the definition. There is no limit to the number of base populations that can be defined. And scales simply defined through use of the distribution assumption on one population cannot be expected to match those based on other populations.

A more appealing basis for establishing interval or ratio properties is provided by fundamental measurement procedures. In these procedures, the meaning of the properties of the final scale is determined, at least to some extent, by the empirical relations between the observables. Fundamental measurement procedures involve verifiable scientific models or theories, place restrictions on the behavior of the observables, and are subject to empirical test. One possible outcome of an application of a fundamental procedure, of course, is the conclusion that the scale in question does not fit the data, that the theoretical assumptions are not appropriate for that particular situation. Under these circumstances, no scale is obtained. But when the empirical fit of data to the theory is acceptable, the result is a scale whose properties are based to some extent on empirical law rather than arbitrary definition alone. It is with such fundamental measurement procedures in scaling that this article is concerned.

**Two broad classes of scaling models.** The fundamental scaling procedures can be grouped into two broad classes: those concerned with the measurement of stimulus attributes and those concerned primarily with measurement of individual difference or responder attributes. Different models within each class represent alternative rationales for attaining essentially the same objective. The objective itself ordinarily differs between classes.

### Stimulus models

The stimulus models use responses of subjects to stimuli to establish scales for attributes of stimuli. Scale values are assigned only to the stimuli. The subject, or group of subjects, is characterized by the entire scale. Individual or group differences in this context refer to *differences between scales*, and not to differences in scale values on the attribute. The stimulus models are therefore concerned with psychological attributes of stimuli for subjects or groups of subjects.

In the stimulus model, the subject himself acts as a judge or evaluator of the stimuli. His task is a particularized one—he does not simply judge or

respond to the stimuli *per se* but, rather, evaluates the stimuli with respect to some specified attribute. Hence, the same set of stimuli can be scaled with respect to several different attributes. A set of statements all designed to reflect an attitude toward some topic might, for example, be scaled with respect to such attributes as degree of favorability toward the topic, relevance, complexity, or intensity. The subject's task in each case is to evaluate the stimuli solely with respect to the attribute of interest. The resulting scale is then indicative of how these particular statements are perceived with respect to the defined attribute by that particular subject or group of subjects.

Stimulus models are used to obtain both psychophysical and psychometric scales. The models appropriate for psychometrics are actually a subset of the psychophysical models, but the measurement problem itself differs considerably in the two fields. Measurement in psychophysics has been concerned primarily with determining functional relations between physical variables and the corresponding subjective attributes. The usual experimental strategy holds constant or controls all relevant physical dimensions but one, and then determines how the subjective attribute varies as a function of that single physical variable. The resulting psychophysical magnitude function is thus a relation between two variables that is expected to hold when other physical variables influencing the subjective attribute are fixed or controlled as specified. For example, a psychophysical function for loudness might relate the perceived loudness of 1,000-cycle sinusoidal tones of a given duration to sound energy measured at the ear. Other functions ordinarily are needed for white noise, for clicks, or for tones of another duration or a different frequency. Although each separate function is monotonic for the relevant physical variable, no such simple relation exists relating sound energy to subjective loudness for stimuli that vary on several relevant dimensions. Development of equations specifying the loudness of any stimulus that possesses sound energy would be a great deal more complex. [See HEARING; PSYCHOPHYSICS.]

In psychophysics the physical variable determines the set of stimuli to which the results apply. In psychometrics, it is more nearly the reverse. Psychometric scaling begins with the psychological attribute. The procedures are applicable to any set of stimuli possessing the attribute, and the problem is to scale the set of stimuli as it exists. The stimulus set is typically complex, varying with respect to other subjective dimensions and with respect to a host of correlated physical variables. There is, of

course, no single, monotonically related physical correlate. Monotone relations are to be expected only when all but one of the physical correlates are held constant. Complexity of the stimulus set is therefore the chief characteristic distinguishing psychophysical from psychometric scaling problems. Several major consequences of this complexity are listed below. [See PSYCHOMETRICS.]

*Recognizability of individual stimuli*—The subject can often identify psychometric stimuli because of their variation on extraneous attributes. Since he may tend to remember earlier responses to the same stimulus, independent judgments on successive trials cannot routinely be expected. Replication over trials with the same subject is therefore troublesome. Most psychometric scales have been based on groups of subjects, so that the recognition problem is not so severe.

*Ordinal properties*—When there is awareness of a monotonically related physical variable, knowledge of order on the subjective attribute is automatically implied. For the complex stimulus sets of psychometrics, order of the stimuli is typically an unknown that must be determined. Experimental procedures that require prior knowledge of order of the stimuli often then cannot be used.

*Production techniques*—When a physical variable is monotonically related to a psychological attribute, there is ordinarily a procedure for easily generating a virtually continuous set of stimuli that are ordered with respect to the psychological attribute. This in turn makes possible the use of the various production techniques—procedures that require the subject to adjust a variable, i.e., to generate a new stimulus, with specified properties. On the other hand, with psychometric stimuli such production techniques typically cannot be used: the subject cannot on demand paint a painting halfway between two standards in aesthetic quality, write an essay twice as good as a standard, or create a worker whose merit falls between that of two others.

*Interpolation*—A monotonic physical attribute can be used as a basis for interpolation. The stimulus that could be judged greater than a standard 75 per cent of the time can be estimated from data obtained by using other stimuli. In addition, a subset of stimuli can be used to establish the functional relation between the two variables. Given the relation, the scale values of all remaining stimuli can be determined numerically or graphically, without resort to additional experimental observations. Neither technique is available for the complex stimulus sets of psychometrics, the closest approximation of which is the establishment of a scale of

standards against which new stimuli can be evaluated by direct comparison.

The stimulus scaling models can be classified into two types on the basis of the rationale used to obtain scale properties above and beyond order. In the *variability* models, the discriminability of the stimuli, or the variability of judgment with respect to the stimuli, is used as the basis for deriving the higher-level metric scale properties. In the *quantitative judgment* models, the additional metric properties are obtained directly from the quantitative aspects of the judgments themselves.

**Variability models.** Perhaps the best-known variability model is that developed by Thurstone (1927). Thurstone's general model begins with a set of elements called *discriminal processes*. Each element has a value on a postulated, underlying psychological continuum. Presentation of a stimulus to a subject results in arousal of a discriminational process. Different presentations of the same stimulus may arouse different discriminational processes—there is thus no one-to-one relation between the two. Rather, a distribution of discriminational processes is associated with each stimulus. Presentation of a stimulus is equivalent to sampling a discriminational process from the distribution associated with that stimulus. [See CONCEPT FORMATION; LEARNING, article on DISCRIMINATION LEARNING.]

In Thurstone's model it is postulated that these distributions (one for each stimulus) are normal with means  $s_i$  and variances  $\sigma_i^2$ . The mean is taken as the scale value of the stimulus. The standard deviation,  $\sigma_i$ , called the *discriminational dispersion*, is the index of the ambiguity or confusability of the stimulus; the smaller the  $\sigma_i$ , the less ambiguous and the more readily discriminable the stimulus. The general model, therefore, provides both location and spread parameters for the stimuli. The conceptual framework of the model is illustrated in Figure 1.

We will consider here two particularizations of

Figure 1 — Distributions on the psychological continuum of discriminational processes associated with four stimuli

Source: From Torgerson 1958, p. 157.

the Thurstone model, one developed for comparative judgments and another developed for categorical judgments.

**The law of comparative judgment.** The law of comparative judgment postulates that in any comparison of two stimuli, the psychological difference between the stimuli is indirectly measured by the relative frequency with which the difference is perceived. For example, two stimuli,  $j$  and  $k$ , are presented to the subject, with instructions to indicate which one appears greater with respect to some designated attribute. Since each stimulus is held to arouse a discriminational process,  $d_j$  or  $d_k$ , the subject selects as greater the stimulus which on that occasion arouses the discriminational process having the greater value on the underlying continuum.

If the difference  $d_k - d_j > 0$ , stimulus  $k$  is selected; if  $d_k - d_j < 0$ , stimulus  $j$  is selected. Exact equality is not allowed. Each paired presentation is formally equivalent to drawing an element from a bivariate normal distribution. An indefinitely large number of such observations generates a distribution of *discriminational differences*. From a large number of such judgments one can also determine the proportion of times that stimulus  $k$  is judged greater than stimulus  $j$ .

One of the characteristics of the normal distribution that makes it particularly valuable for distribution models of this type is that differences between paired observations drawn from a bivariate normal distribution are normally distributed. The mean of the difference distribution is equal to the difference between the original means, or scale values,  $s_k - s_j$ ; the variance is  $\sigma_j^2 + \sigma_k^2 - 2r_{jk}\sigma_j\sigma_k$ , where  $r_{jk}$  represents the correlation between the pairs of discriminational processes. If we define  $p_{jk}$  as the probability that stimulus  $k$  is judged greater than stimulus  $j$  (that is, that  $d_k - d_j > 0$ ) on any given presentation, and define  $x_{jk}$  as the unit normal deviate corresponding to  $p_{jk}$ , then the general form of the law of comparative judgment for  $n$  stimuli is given by the set of equations

$$(1) \quad s_k - s_j = x_{jk} \sqrt{\sigma_j^2 + \sigma_k^2 - 2r_{jk}\sigma_j\sigma_k}, \\ j, k = 1, 2, \dots, n.$$

The quantity  $x_{jk}$  is the (theoretical) observable; the remaining terms are unknowns. Given  $n$  stimuli, there are  $n(n-1)/2$  possible equations and, since both the origin and unit are arbitrary, there are  $2(n-1) + n(n-1)/2$  unknowns. Hence there are always more unknowns than independent equations, and further restrictions on the data are necessary to establish scale values. Three such specializations have been proposed, of which only one, Thurstone's case v, the most restrictive, has been

found generally useful. In case v, it is assumed that the value under the radical in (1) is constant, i.e., that the distributions of discriminial differences all have the same variance. Then, arbitrarily defining the variance as unity, for convenience, there remain simply the  $n(n-1)/2$  equations

$$(2) \quad s_k - s_j = x_{jk}, \quad j, k = 1, 2, \dots, n.$$

Efficient procedures for estimating the scale values from these equations are available. The scale obtained is an interval scale, because the unit of measurement must be defined arbitrarily, and a constant can be added to all of the scale values without changing the solution. Furthermore, the interval properties are based on empirical law. Consider any three ordered stimuli,  $i < j < k$ , and the three unit normal deviates  $x_{ij}$ ,  $x_{jk}$ , and  $x_{ik}$ . From (2), since the numerical differences between scale values must add,

$$(s_k - s_j) + (s_j - s_i) = (s_k - s_i), \quad \text{for all } i < j < k,$$

it is clear that the model requires that

$$(3) \quad x_{jk} + x_{ij} = x_{ik}, \quad \text{for all } i < j < k.$$

The additivity-of-difference rule can therefore be said to provide the empirical basis for the interval properties of the final scale. Actually, of course, one would not expect (3) to hold exactly for empirical data. Among other things, the obtained proportions on which the deviates are based are only estimates and not population values. A statistical test for the goodness of fit of the model to data has been provided by Mosteller (1951). Graphical and numerical procedures can also be used to aid the investigator in deciding whether the fit is close enough for his purposes even though it does not meet the statistical criterion. Given estimates of the scale values of the stimuli, one can compute the set of theoretical proportions that would fit the estimated scale values perfectly. The discrepancies between these derived proportions and the corresponding observed proportions can then be examined. Alternatively, for any two stimuli,  $i$  and  $j$ , one can plot the obtained values of  $x_{ik}$  versus  $x_{jk}$  for all values of  $k$ . From (2) it is clear that the model requires that the plotted points fall along a straight line with unit slope. [See GOODNESS OF FIT.]

*The law of categorical judgment.* Several additional postulates are used to adapt the general Thurstone model to categorical data and to derive a set of equations relating stimulus values and category boundaries to the relative frequency with which each stimulus is judged to be in each category. In the usual experimental procedures, the

subject is required to rate or sort a set of  $n$  stimuli into a fixed number of ordered categories. Graphic rating procedures or arrangement methods can also be used, but these require that the data first be artificially divided into a limited set of ordered categories.

Thurstone's general model illustrated in Figure 1 deals with a set of  $n$  stimuli and their associated distributions of discriminial processes, with means  $s_j$  and standard deviations  $\sigma_j$ . The present extension adds parallel notions dealing with the location of boundaries between adjacent categories.

Data are presented in the form of ratings of stimuli on an  $m+1$  step scale. It is assumed that the psychological continuum is divided by the  $m$  category boundaries into  $m+1$  intervals, which may or may not be equal in extent. In the original version of the model, the boundaries were treated as fixed. We shall follow the more general version that allows the boundary locations to vary from observation to observation. The location of the  $g$ th category boundary is treated as a random variable with mean  $t_g$  and variance  $\sigma_g^2$ . If we assume that these distribution functions are also jointly normal, then precisely the same reasoning that led to (1) leads to the set of  $mn$  equations for the general law of categorical judgment:

$$(4) \quad t_g - s_j = x_{jg} \sqrt{\sigma_j^2 + \sigma_g^2 - 2r_{jg}\sigma_j\sigma_g}, \\ j = 1, 2, \dots, n, \\ g = 1, 2, \dots, m,$$

where  $t_g - s_j$  denotes the difference between the mean location of category boundary  $g$  and the mean location of stimulus  $j$ . Eq. (4) is again too general to be of more than academic interest. As was true for (1), there are always more unknowns than equations. One common restricted version of the general equation is based on the assumption that the radical is a monotone function of the stimulus standard deviations,  $\sigma_j$ . This would occur, for example, if both the correlation term and the variances of the category boundaries were constant, or if constant variances  $\sigma_g^2$  and independence ( $r_{jg} = 0$ ) were assumed. If we now let

$$\alpha_j^2 = \sigma_j^2 + \sigma_g^2 - 2r_{jg}\sigma_j\sigma_g,$$

we can then write the  $nm$  equations

$$(5) \quad t_g - s_j = x_{jg}\alpha_j, \quad j = 1, 2, \dots, n, \\ g = 1, 2, \dots, m.$$

Eqs. (5) are formally identical to the equations underlying the "method of successive intervals" (Saffir 1937; Gulliksen 1954), although in the traditional version the assumption of fixed boundaries leads to the interpretation of  $\alpha_j$  as the standard

deviation (discriminal dispersion) of stimulus  $j$  rather than as a more general spread parameter only monotonically related to  $\sigma_j$ .

Efficient and practical estimation procedures have been developed for both complete and incomplete data matrices and are discussed in Torgerson (1958).

Another common restricted case assumes that the difference distributions all have the same variance. Then, if the unit of measurement is defined so that the value under the radical in (4) is 1, we can write the  $nm$  equations,

$$(6) \quad t_{ij} - s_j = x_{ij}, \quad \begin{matrix} j = 1, 2, \dots, n, \\ g = 1, 2, \dots, m. \end{matrix}$$

Eqs. (6) represent the most restricted version of the law and underlie Attneave's method of graded dichotomies (1949), Garner and Hake's equidiscriminability scaling procedure (1951), and Edwards and Thurstone's method of successive intervals (1952). Note that this version allows a single parameter for both stimuli and category boundaries, whereas the other version allowed a second parameter for the stimuli. The final scale, if achieved, is therefore an equidiscriminability or equiconfusability scale, with properties similar to those of (2) for comparative judgments.

*The logistic model for choice data.* The logistic model is the major alternative to Thurstone's general model for obtaining a scale based on discriminability or variability of judgment. The model was developed for the paired comparison case by Bradley and Terry (1952). Luce's choice axiom (1959) extended the model to choice data in general and gave the procedure a more elegant, axiomatic basis.

Luce's version of the model requires, in essence, that the subjects' choices behave in a manner analogous to conditional probabilities. Where  $S$  and  $T$  are both subsets of a set  $U$  and where  $p(T)$ , the probability of choosing an element of  $T$ , is greater than 0, then the formula for the conditional probability of  $S$  given  $T$ ,  $p(S|T)$ , is  $p(S \cap T)/p(T)$ . The interesting property of conditional probability for present purposes is the multiplication rule. Given three subsets, such that  $R \subset S \subset T$ ,

$$p(R|S) \cdot p(S|T) = p(R|T).$$

Luce's axiom, for the case where the probability of choosing any element is neither 0 nor 1, is the empirical analogue:

$$(7) \quad p_S(R) \cdot p_T(S) = p_T(R).$$

That is, the probability that the subject will choose an  $R$ -element when presented with the set  $T$  is equal to the probability that he will choose an  $R$ -

element when presented with the set  $S$  multiplied by the probability that he will choose an  $S$ -element when presented with the set  $T$ .

An alternative form of the axiom is known as the constant ratio rule (Clarke 1957). Let  $x$  and  $y$  denote any two stimuli, let  $p(x, y)$  denote the probability that stimulus  $x$  is chosen when only  $x$  and  $y$  are presented, and let  $p_S(x)$  denote the probability that stimulus  $x$  is chosen when the subset  $S$  is presented. The constant ratio rule states that

$$(8) \quad \frac{p(x, y)}{p(y, x)} = \frac{p_S(x)}{p_S(y)} = C_{xy},$$

where  $C_{xy}$  denotes the constant ratio of the probability of choosing stimulus  $x$  to the probability of choosing stimulus  $y$ . The rule requires that for any set  $S$  containing both stimulus  $x$  and stimulus  $y$ , the ratio of the probability of choosing stimulus  $x$  to that of choosing stimulus  $y$  be invariant. For a given pair of stimuli the ratio is constant regardless of either what or how many other stimuli are included in the set from which the choice is made. The complete experiment for evaluating Luce's axiom or the constant ratio rule would therefore require the experimenter to obtain separate estimates of the probability of choosing stimulus  $x$  (for all  $x \in T$ ) for every subset of  $T$  containing  $x$  as a member.

When the requirements of the axiom are met, then there exists a  $v$ -scale such that for every subset of stimuli  $S$ ,

$$(9) \quad p_S(x) = \frac{v(x)}{\sum_{y \in S} v(y)},$$

where  $v(x)$  denotes the scale value of stimulus  $x$ . From (9) and the constant ratio rule it is also clear that

$$(10) \quad \frac{v(x)}{v(y)} = \frac{p_S(x)}{p_S(y)} = \frac{p(x, y)}{p(y, x)}.$$

Given the axiom and the definition, the scale values are determined up to multiplication by a positive constant, i.e., the  $v$ -scale is a ratio scale. It should be noted, however, that the ratio property depends on the particular definition chosen, as well as on the requirements placed on the data by the axiom. The empirical requirements of the choice axiom may limit the scale to determination up to a multiplicative constant and an exponent. Eq. (9), in effect, specifies a particular exponent in the same way that the unit was specified in (2).

The axiom places two rather severe restrictions on the data. Consider first the paired comparison case, and let  $x, y, z$  denote any three stimuli. Then

the probability ratios must follow a multiplication rule:

$$(11) \quad \frac{p(x,z)}{p(z,x)} = \frac{p(x,y)}{p(y,x)} \cdot \frac{p(y,z)}{p(z,y)}.$$

Hence, any two probabilities determine the third. It can also be shown that the pairwise probabilities determine all probabilities of choice from larger sets and, in fact,

$$(12) \quad p_s(x) = \frac{1}{\sum_{y \in S} \frac{p(y,x)}{p(x,y)}}.$$

An adequate test of the model as stated would require evaluation of the extent to which both restrictions are met.

The simpler version of the logistic model, as developed by Bradley and Terry, is limited to paired comparison data and, hence, only the first restriction is applicable. Efficient estimating procedures and tests of goodness of fit are available (Bradley & Terry 1952; Bradley 1954).

*Thurstone's case V and the logistic model.* If we consider only the paired comparison situation, then the equation relating scale values to observable proportions for the logistic model can be written simply as

$$(13) \quad p(x,y) = \frac{v(x)}{v(x) + v(y)}$$

or, equivalently, as

$$(14) \quad \frac{v(x)}{v(y)} = \frac{p(x,y)}{p(y,x)}.$$

Eq. (14) shows that in the  $v$ -scale a simple function of the observable is interpreted as a ratio of scale values. From (11) it is apparent that the metric properties of the  $v$ -scale are based on a multiplication-of-ratios rule, with log interval properties. In Thurstone's case  $v$ , the corresponding basis for the metric properties was an additivity-of-differences rule, which yielded an interval scale.

Bradley and Terry, as well as Luce, have shown that the logistic model can also be used to generate an interval scale based on additivity of differences. If one defines  $r(x) = \ln v(x)$  and  $w(x,y) = r(x) - r(y)$ , then (14) can be written

$$(15) \quad \ln \frac{p(x,y)}{p(y,x)} = r(x) - r(y) = w(x,y),$$

and from (13),

$$(16) \quad p(x,y) = \frac{1}{1 + e^{-w(x,y)}},$$

which is a simple form of the logistic function.

The logistic function and the normal ogive are markedly similar over most of the empirically in-

teresting range. As a result, a close fit of the data to Thurstone's case  $v$  insures a fit to the logistic model that can be only trivially better or worse. For all practical purposes, the values from the  $r$ -scale of the logistic model will be linearly related to the scale values from the Thurstone case  $v$  model. And both, of course, will be logarithmically related to the  $v$ -scale values.

It might be noted that the Thurstone model can also be easily modified to yield a log interval scale similar to the  $v$ -scale of the logistic model. We need only to substitute log normal distributions for normal distributions and subjective ratios for subjective differences. The new scale will be exponentially related to the Thurstone case  $v$  scale, and will therefore be related to the  $v$ -scale by a power transformation. In general, any model in which the observable is interpreted as a subjective difference in scale values can be paralleled by one in which the observable is interpreted as a subjective ratio. The difference-based scale will be logarithmically related to the ratio-based scale, and the fit of one model to any given set of data will be precisely matched by the fit of the other, parallel model.

*Quantitative judgment models.* The variability methods require only ordinal judgments by the subject; the higher-level, metric properties of the obtained scales are derived through models relating variability of judgment to subjective differences or ratios. In the quantitative judgment models, the higher-level properties are obtained *directly* from the subject's judgments. There are two classes of quantitative judgment methods: the difference, or distance, methods and the ratio methods. The difference methods have long been used to develop scales in the social sciences (Thurstone & Chave 1929). Serious application of the ratio methods in the context of social science is more recent (see, for example, the summary of research in Stevens 1966). In the difference methods, the metric properties of the obtained scale depend upon the ability of the subject to evaluate or equate subjective differences. In the ratio methods, the metric properties depend upon his ability to evaluate or equate subjective ratios. Scales obtained from the two types of procedures are not ordinarily linearly related.

*Difference methods.* Difference methods include the methods of equisection, equal-appearing intervals, category rating, and category production. The methods differ from one another in the specific nature of the experimental procedure employed, but they all have the same objective: to obtain a scale in which the differences in numbers assigned to the stimuli directly reflect the corresponding subjective differences between the stimuli.

In equisection, the subject produces a set of stimuli that divides a given range of the attribute into subjectively equal steps. In equal-appearing intervals and category rating he sorts or rates the stimuli into a given set of subjectively equally spaced steps or categories. In category production, he produces on each trial a stimulus that corresponds to one of a set of equally spaced categories.

The usual procedures do not include built-in checks for the adequacy of the assumption that the subject can produce such judgments in an internally consistent manner. The assumption does place empirical restrictions on the behavior of the judgments, however, so appropriate checks are possible. The simplest and most direct check uses the method of bisection. Here, the subject first bisects the interval between two standard stimuli,  $a$  and  $e$ , to produce a new stimulus,  $c$ , halfway between. He next bisects the interval  $a-c$ , producing a stimulus  $b$ , and bisects the interval  $c-e$ , producing a stimulus  $d$ . Finally, he bisects the interval between  $b$  and  $d$ . If the subject's bisections are made in an internally consistent manner, the stimulus produced by the final bisection between  $b$  and  $d$  will be equal to  $c$ , the stimulus produced by the bisection of  $a$  and  $e$ .

For psychometric stimuli, where production techniques are unavailable, a more or less equivalent procedure involves imbedding a given subset of stimuli in several different larger sets. If the subject's rating or sorting judgments fulfill the requirements of an interval scale, the scale values assigned to the members of the subset will be linearly related across the several experiments.

*Ratio methods.* Ratio methods include the methods of fractionation, constant sum, magnitude and ratio estimation, and magnitude and ratio production. In all of these methods, the subject's task is to adjust stimuli or assign numbers so that the ratios between the numbers correspond to the subjective ratios between the stimuli. In fractionation, the subject adjusts a variable to be equal to  $1/k$  of a standard. In the constant sum method, he divides 100 points between two standards so that the ratio between the assigned points corresponds to the subjective ratio. In the magnitude estimation procedure, his task is to assign numbers so they are proportional to the subjective magnitudes, whereas in the ratio estimation method, he assigns numerical ratios to pairs of stimuli. In the corresponding production procedures, the roles of numbers and stimuli are reversed: the experimenter chooses the numbers and the subject produces the appropriate stimuli or stimulus ratios.

Only the constant sum method has a built-in

check for adequacy of the basic assumption. But again, appropriate checks of internal consistency are available for the other methods and, in fact, parallel those for the difference methods.

*Differences versus ratios.* The logarithmic, or nearly logarithmic, empirical relationship between difference scales and ratio scales has led to the conjecture that the subject's quantitative judgments are based on a single perceived quantitative relation (Torgerson 1961). According to this argument, when the subject is told to equate differences, he interprets the subjective relation as a difference. When he is told to equate ratios, he interprets the same relation as a ratio. The conjecture receives additional support from the behavior of quantitative judgments when the direction of the attribute is reversed, i.e., when the subject reports on smoothness rather than roughness, or darkness rather than lightness. For difference scales, the attribute and its reverse are linearly, though negatively, related. Stimuli that are separated by equal differences in one direction remain equally different when the direction of judgment is reversed. For the ratio scales, the attribute and its reverse are reciprocally related. Here the equal ratio property is invariant, but differences of course change markedly.

The empirical results based on quantitative judgment are thus similar to the formal limitations of the variability methods. Each set of procedures yields scales on which either differences or ratios, but not both, are empirically meaningful. Additional procedures seem necessary to obtain a scale where both relations have an empirical basis. One such procedure has been devised by Cliff (1959).

### Individual difference models

The individual difference, or responder, models use subjects' responses to stimuli as a way of establishing scales for attributes on which the subjects (responders) themselves differ. The models are based upon individual differences; an ultimate aim is to assign scale values to the subjects to represent amount or degree of the attribute possessed by each. Stimuli may also be assigned scale values on a parallel attribute, or they may be assigned parameter values relating them in some more general manner to the attribute of interest. Individual difference models are therefore those in which a response to a stimulus is interpreted as a function of both the scale value of the responder and the parameter values of the stimulus.

The relation between the task set for the subject and the attribute continuum differs markedly between the stimulus models and the individual dif-

ference models. In the stimulus models, the task is a particularized one—the subject evaluates stimuli with respect to the attribute being measured. In the individual difference models, the task itself has no obvious relation to the underlying attribute. In the *categorical response* methods, the subject simply indicates whether or not (or the extent to which) he agrees with, likes, or can pass a particular item. In the *comparative response* methods, he indicates which item he agrees with most, or which he prefers. In neither case, however, is the attribute of interest one of agreement or preference. It is, rather, a latent or underlying attribute that serves to explain or account for the variation in the responses of the subjects to the stimulus items.

A concrete example might serve to clarify the distinction. Suppose we are given a set of samples of coffee that differ *only* in the amount of sugar that has been added. The samples are presented, two at a time, to a population of subjects. Each subject chooses the member of each pair that he prefers. If a *stimulus* model were successfully applied to the data, the result would be a scale of *preferability* of the samples, ranging from the least preferred to the most preferred for that population of subjects. But if an *individual differences* model were successfully applied to the data, the result would be a scale of *sweetness*, with the stimuli ranging from least sweet to most sweet and *each subject characterized by a scale value denoting the degree of sweetness that he considers ideal*. The subjects' responses do not tell us, of course, that the underlying variable is degree of sweetness. If the coffee samples had varied in strength or in amount of cream added rather than in sweetness, their responses would still have been of exactly the same form. In general, the individual differences models are explicitly concerned solely with the question of whether or not the responses of a given group of subjects to a given set of stimuli can be accounted for by a single underlying attribute. They do not tell one how to select the stimuli in the first place or, given that the stimuli form a scale, how the underlying attribute should be interpreted.

Individual differences models can be classified in a number of ways. One important difference, which will be used to organize the remainder of this section, is the distinction between the simple *deterministic* models and the more elaborate *probabilistic* models. Deterministic models are developed in terms of the ideal case; there is no provision in the model itself for unsystematic variance. Since the ideal case virtually never occurs, the empirical question is one of the extent to which the ideal approximates the actual behavior of the subjects.

The probabilistic models represent more realistic attempts to account for the behavior of the subjects, provide explicitly for unsystematic variance, and, at least theoretically, lend themselves to statistical evaluation of goodness of fit.

**Simple deterministic models.** Three general models will be considered here: Coombs's distance models for preferential choice data, Guttman's scalogram model for categorical responses to monotone items, and the scalogram models for categorical responses to point items.

**Distance models.** In Coombs's distance models, both subjects and stimuli are represented as points along an underlying, latent continuum. According to the general model, the subject's preferential choices among stimuli are determined by the relative distances of the stimuli from that subject. A stimulus located at the same point as the subject represents his ideal, the one he would prefer above all others. As distance from the subject increases, the desirability of the stimulus to that subject decreases. Subject A thus will prefer stimulus X to stimulus Y when the distance  $d_{AX}$  is less than the distance  $d_{AY}$  on the underlying continuum.

Any of a large number of experimental procedures might be used to obtain a preferential ranking of the stimuli—called a *qualitative I-scale*—for each subject. The analytical problem is to determine whether the set of I-scales could have been derived from distances between subjects and stimuli on a common underlying attribute, and, if so, to construct the joint scale—or *J-scale*—giving the required locations of stimuli and subjects. Coombs's *unfolding technique* (1950; 1964) is a procedure for accomplishing this goal. The end result is a scale which orders the stimuli, orders the midpoints between pairs of stimuli, and locates the subjects in segments of the scale defined by the interval between adjacent stimulus midpoints.

The order of the midpoints provides information on the relative size of the intervals between some, but not all, of the stimuli. For example, given four stimuli in order ABCD, the midpoint between B and C precedes that between A and D, when the distance  $d_{BC} > d_{AD}$ . Scales such as this, which provide not only an order for the elements themselves but also an order for some of the distances between elements, are called ordered metric scales.

With suitable modifications (Coombs 1953), the general approach described above can also be applied to data obtained from the "order  $k|n$ " and "pick  $k|n$ " methods. In the "order  $k|n$ " methods, the subject rank-orders only the first  $k$  out of the  $n$  stimuli presented to him, and in the "pick  $k|n$ " methods, he simply chooses the  $k$  out of  $n$  stimuli

he prefers most. Procedures for ordering the stimuli and for locating the subjects in ordered classes are given in Coombs (1953) and Torgerson (1958).

*Monotone and point scalogram models.* The scalogram models for categorical data are concerned with subjects and items, where an item is defined as any stimulus or procedure that partitions the set of subjects into two or more mutually exclusive categories. In these models, both subjects and category boundaries can be considered as points on an underlying continuum. The scaling problem is to determine whether the subjects and category boundaries can be positioned along the continuum so that all subjects are located within the appropriate categories of all items.

Three types of ideal items are of interest: the monotone multicategory item, the monotone dichotomous item, and the nonmonotone, or point, item.

A *monotone item* divides the underlying continuum into as many segments as there are response categories, with each category corresponding to one and only one segment. The following multicategory item provides an example of the general form:

My weight is (a) between 150 and 175 pounds;  
(b) 150 pounds or less; (c) 175 pounds or more.

*Dichotomous monotone items* provide only two response alternatives. For example,

I weigh over 150 pounds.      True \_\_\_\_\_  
False \_\_\_\_\_.

Different items ordinarily partition the underlying continuum in different places. In general,  $n$  monotone items, with a total of  $m$  categories in all, partition the underlying continuum into  $m - n + 1$  segments.

Guttman's general scalogram procedure (see Stouffer et al. 1950) is a routine for determining whether the  $n$  items (a) are monotonic and (b) can be considered as partitioning the same underlying attribute for the given population of subjects. If so, the final result is, first, a rank order of the item category boundaries on the underlying continuum and, second, the locations of subjects in the segments defined by adjacent category boundaries. The general procedure can be used with any combination of multicategory and dichotomous monotone items. Somewhat simpler procedures are available if all items are dichotomous.

*Nonmonotone, or point, items* also partition the underlying continuum into segments, but not in a one-to-one fashion. An example of one form of nonmonotone item is

My weight is between 150 and 175 pounds.  
True \_\_\_\_\_  
False \_\_\_\_\_.

The positive response to this type of nonmonotone item corresponds to a single segment—in this example, the range from 150 to 175 pounds. But a negative response corresponds to two segments: subjects weighing over 175 pounds and those weighing under 150 pounds both respond negatively.

In order to evaluate the scale hypothesis and to obtain an ordinal scale, it is necessary for the segments corresponding to the positive alternatives to overlap. If no overlap occurs, the data contain information sufficient only to locate the subjects into a set of unordered categories. The procedures for uncovering the underlying scale for nonmonotone items are different from, but conceptually similar to, those appropriate for monotone items.

An alternative ideal model for nonmonotone items treats the positive category of the item as a point and represents each subject by a segment of the underlying continuum. An example of an item which might fit such a model better would be

I weigh about 150 pounds.      Yes \_\_\_\_\_  
No \_\_\_\_\_.

Here, subjects might differ with respect to their ideas of the range encompassed by the term "about." Since the two models are formally equivalent—they differ only in the interchange of the role of subject and item—the same analytical routines are applicable.

*Probabilistic models: the general theory.* Most of the models developed for measuring individual difference attributes can be considered within the framework of a single general probabilistic model whose conceptual basis is essentially that of Lazarsfeld's latent structure analysis (1954; see also Stouffer et al. 1950), in which the attribute to be measured is represented formally by an underlying or latent space of one or more dimensions, subjects are represented by points in the latent space, and the stimuli are treated as variables. Stimuli may be psychological test items, attitude statements, rating scales, or, in general, anything that classifies the subjects into two or more exclusive and exhaustive categories. The observations, or *manifest data*, thus consist of an  $N$  by  $n$  matrix of the scores of the  $N$  subjects on the  $n$  stimuli. The stimulus variables are characterized in the general model by the parameters of the equation describing the regression of that variable on the underlying latent attribute.

An important general notion is the principle of local independence. Since each stimulus variable is related to the underlying attribute, the stimulus variables will be related to each other in some fashion. The principle of local independence re-

quires that the systematic relations among the stimuli be accounted for entirely by the separate relations of each stimulus variable to the underlying attribute. Thus, at any given point in the latent space, the stimuli are all mutually independent.

The over-all theory or conceptual framework clearly is completely general. In order to turn it into a testable model—one which places restrictions on the data—additional postulates or conditions are necessary. Three important considerations are the nature of the manifest data required, the nature of the postulated latent attribute, and the form of the regression equation relating the stimulus variables to the latent attribute. A particular model or testable specialization of the general theory depends on making a decision about each of the three. [See LATENT STRUCTURE.]

Three levels or types of manifest response data are of major concern here, but obviously others are possible: *Dichotomous items*—the stimulus variable classifies the subject into one of two categories; *ordered classes*—the stimulus variable classifies the subject into one of several ordered categories; *interval scale*—the stimulus variable provides an interval scale value for the subjects.

Three restrictive assumptions that can be placed on the postulated latent attribute are the following: the subjects are assumed to be located only at a relatively small number of points or regions in the space; the underlying attribute is assumed to be unidimensional; and the underlying attribute is assumed to be a multidimensional Euclidean space.

Four types of regression equations that relate the stimulus variables to the latent attribute are the various step functions, the linear equation, the normal ogive equation, and the logistic equation.

The models also differ in whether or not they provide for or allow variance about the regression line or surface. The distinction here is essentially that made earlier between deterministic and probabilistic models. The deterministic models for categorical data, which make no provision for extraneous variance, can be considered as limiting cases for certain of the probabilistic versions.

Some specializations of the general theory. All of the models described in this section can be treated as specialized instances of general regression theory. In all cases, subjects can be considered as points in an underlying attribute space, stimuli as manifest variables related to the underlying space by a regression equation, and interrelations between manifest variables in terms of their separate relations to the underlying attribute space. The models differ in the kind of data required, the kind of space allowed, the form of the postulated regression equation, and in whether or not explicit provision is made for variance about the postulated regression surface. Table 1 provides a summary of the characteristics of and differences between a number of the more common models.

*Lazarsfeld's latent class model.* In Lazarsfeld's latent class model the stimuli (items) are dichotomous and are scored either as 0 or as 1. The latent space is nominal—subjects are located at discrete

Table 1 — Characteristics of some individual difference models that fall within the general regression approach

	DETERMINISTIC			PROBABILISTIC							
	General scalogram	Dichoto- mous scalogram	Multidi- mensional extensions of scalogram	Latent class	Latent profile	Latent distance	Linear	Two- factor	Multiple factor analysis	Normal ogive	Logistic
Observable											
Dichotomous		X	X	X			X			X	X
Ordered classes	X										
Interval					X			X	X		
Latent space											
Points				X	X						
Unidimensional	X	X									
Multidimensional			X			X	X	X		X	X
Regression									X		
Step function	X	X	X	X	X	X					
Linear								X	X	X	
Normal ogive											
Logistic										X	
Variance about regression											
Yes				X	X	X	X	X	X	X	X
No	X	X	X								

points or, equivalently, along arbitrarily ordered intervals of a unidimensional continuum. The regression equation is then a step function, and provision is made for variance about the regression line.

If the classes are ordered arbitrarily, the height of the regression line for an item  $j$ , over the interval defined by class  $s$ , is the average score of the subjects in class  $s$  on that item. Since only scores of 0 and 1 are used, the height of the regression line for class  $s$  is also the probability that a person in class  $s$  will answer item  $j$  correctly. This probability is denoted by  $v_{js}$ . The unknowns to be determined are the set of probabilities  $v_{js}$  and the proportion of subjects in each class,  $\pi_s$ .

The observational information can be expressed by the following set of manifest proportions:

$p_j$  = the proportion of subjects in the entire sample answering item  $j$  positively;

$p_{jk}$  = the proportion of subjects answering both item  $j$  and item  $k$  positively;

$p_{jkl}$  = the proportion answering items  $j$ ,  $k$ , and  $l$  positively;

$\vdots$   $\vdots$

Lazarsfeld has shown that this information can be incorporated into a set of accounting equations, and several procedures have been devised for solving such equations (Green 1951; Anderson 1954). The solutions themselves do not directly indicate the class membership of individual subjects but, rather, give only the proportion of subjects in a class. Additional procedures are needed to assign subjects to classes.

**Gibson's latent profile model.** Gibson's latent profile model (1959), which differs from Lazarsfeld's only in the type of data required, is designed for manifest responses measured on an interval scale. Since the equations for latent profile analysis are formally identical to those of latent class analysis, no new analytical procedures are needed for their solution.

**Lazarsfeld's continuous models.** In Lazarsfeld's continuous models the stimuli are dichotomous items scored either as 0 or as 1, but the latent space is generally assumed to be a unidimensional continuum, although multidimensional extensions have also been suggested. Hence, the several continuous models proposed by Lazarsfeld differ from each other only in the form of the regression line. Where  $x$  = the latent variable,  $f_j(x)$  = the regression of item  $j$  on  $x$ , and  $g(x)$  = the density function of

Figure 2 — Form of item regression or trace line for the latent distance model

Source: From Torgerson 1958, p. 375.

the individuals, Lazarsfeld provides the following set of accounting equations:

$$p_j = \int_{-\infty}^{+\infty} f_j(x) g(x) dx$$

$$p_{jk} = \int_{-\infty}^{+\infty} f_j(x) f_k(x) g(x) dx$$

$$p_{jkl} = \int_{-\infty}^{+\infty} f_j(x) f_k(x) f_l(x) g(x) dx$$

$$\vdots \qquad \qquad \qquad \vdots$$

In the latent distance model, the regression, or trace line, for the items  $j$  is assumed to be a step function of the form shown in Figure 2. It is assumed that the probability of a response is some constant value ( $a_j - b_j$ ) up to a particular point  $x_j$ , and at this point it jumps to another value ( $a_j + b_j$ ) and remains constant thereafter. The equation for the regression can be written

$$\begin{aligned} f_j(x) &= a_j - b_j, & \text{for } x \leq x_j, \\ f_j(x) &= a_j + b_j, & \text{for } x > x_j. \end{aligned}$$

Each item is thus represented by three parameters:  $a_j$ ,  $b_j$ , and a break point,  $x_j$ .

It is a general rule that step-function regression lines provide no metric information about the shape of the underlying distribution of subjects. Any monotonic transformation of the underlying continuum leaves the form of such regression lines unchanged; hence, the final scale is ordinal. Solutions for the latent distance model have been provided by Hays and Borgatta (1954).

It is interesting to note that if the parameters  $a_j$  and  $b_j$  are both assumed to have values of  $\frac{1}{2}$  for all items, the latent distance model reduces to Guttman's scalogram model for dichotomous items.

Lazarsfeld's linear model assumes that the regression lines can be represented by an equation of the form

$$f_j(x) = a_j + b_j x,$$

where  $0 \leq f_j(x) \leq 1$  for all items over the region of the continuum containing the distribution of subjects. Solutions for the item parameters  $a_j$  and  $b_j$  are available (see Torgerson 1958).

**Spearman's two-factor model.** Spearman's two-factor model (1927) differs from Lazarsfeld's linear model only in the form of the manifest data. When it is assumed that the stimulus variables are measured on an interval scale and standardized with a mean of zero and unit variance, then one can write the equation

$$s_{ij} = c_{ij}a_{jg} + e_{ij},$$

where  $s_{ij}$  = score of subject  $i$  on stimulus  $j$ ,  $c_{ij}$  = score of subject  $i$  on the general factor  $g$ ,  $a_{jg}$  = loading of stimulus  $j$  on the general factor, and  $e_{ij}$  represents variance due to unique factors and to error.

The regression line can be written simply as

$$f_j(x) = a_jx,$$

which differs from Lazarsfeld's linear model only by the lack of an additive constant.

**Multiple factor analysis.** The standard procedures of multiple factor analysis require manifest data on interval scales and differ from Spearman's model by the substitution of a multidimensional latent space for the unidimensional general factor. The basic equation for the score of subject  $i$  on stimulus  $j$  becomes

$$s_{ij} = \sum_{m=1}^M c_{im} a_{jm} + e_{ij},$$

where  $m = 1, 2, \dots, M$  is an index for dimensions. The corresponding regression function becomes

$$f_j(x) = \sum_{m=1}^M c_{im} a_{jm}.$$

[See FACTOR ANALYSIS; the biography of SPEARMAN.]

**Normal ogive and logistic models.** Normal ogive and logistic models require dichotomous items scored either as 0 or as 1, and assume a unidimensional latent attribute. They differ from the latent distance and linear models in their assumption of regression lines that seem intuitively to be more reasonable, particularly for measuring aptitudes and abilities. Models using the normal ogive trace lines have been developed by Lord (1953) and Tucker (1952). Birnbaum (1957) and Rasch (1960) have worked with the logistic function.

## SCHELER, MAX

Max Scheler (1874-1928), German philosopher and sociologist, was born in Munich. His father came from an upper-middle-class Protestant family which can be traced to the sixteenth century; a number of his forebears had been clergymen and jurists in the city of Coburg. His mother was descended from a Jewish Orthodox family that had been settled in Franconia for many centuries. The clash of religious and cultural traditions in his home may account in part for the strains and tensions in his personality and work.

Scheler studied medicine and philosophy at the University of Jena. There, Rudolf Eucken, the Nobel prize-winning idealistic philosopher and defender of Protestant cultural liberalism, was his most prominent teacher. Scheler's early work, beginning with his dissertation at Jena (1899), where

he became a *Privatdozent* in 1901, clearly derived from Eucken. The distinctive aspects of Scheler's thought became apparent only after he moved to the University of Munich in 1907. There he assimilated the phenomenological method: Franz Brentano, who had been Edmund Husserl's teacher, continued to lecture there in Scheler's day, and Scheler was also influenced by Husserl's eminent disciples at the university. Although he was never an "orthodox" phenomenologist, his subsequent philosophizing moved within the orbit of Brentano's and Husserl's thought. [See the biography of HUSSERL.]

In 1910 Scheler gave up his connection with the University of Munich and moved to Berlin to live as an academically unattached writer. His first major works were written in this Berlin period. Among his close intellectual companions in those days were Walther Rathenau and Werner Sombart. The outbreak of World War I marked a turning point in Scheler's career. He threw himself with great ardor into the defense of the German cause. The articles and books in which he defended the "German war" with passionately nationalistic fervor brought him to the attention of a wider public than had noticed his more scholarly productions. In 1917 and 1918 he worked at various diplomatic and propagandistic tasks for the German Foreign Office in Geneva and The Hague. During the war years Scheler, despite his intense nationalistic commitment to the "fatherland," moved closer to a Christian position in the realm of ethics, becoming finally a Roman Catholic convert.

In 1919 Scheler accepted a call to the chair of philosophy and sociology at the University of Cologne. During the next five years he gradually developed his sociology of knowledge. About 1924 he began slowly to turn away from his previous commitment to Catholicism and eventually left the church. He then began to work on a comprehensive *Anthropologie*, in which he attempted to expound a kind of vitalistic pantheism that he had come to adopt. But he was not able to develop this new conception fully. He accepted a call from the University of Frankfurt in the beginning of 1928, but he died on May 19, 1928, at the age of 54, before assuming his new post.

Quite different strands of thought were woven into the texture of Scheler's thought at different times in his intellectual development. He was ever open to new ideas and did not fear to contradict himself. As a consequence, he failed to achieve a full synthesis of his thought but was able to appeal by virtue of his own intellectual restlessness to the restless young intellectuals of the postwar period.

An erratic man, he was always to be a somewhat disturbing figure to the more settled members of the academic community while he gained considerable influence among younger sociologists and philosophers. Although he did not found a "school," he was a major intellectual pathsetter in pre-Nazi Germany as a social critic and moralist and as a sociologist and philosopher. Since World War II the vogue of phenomenology and existentialism in France has led to vigorous interest there in Scheler's work. In the Anglo-Saxon countries, Scheler was until recently little known, except among scholars interested in the sociology of knowledge or among certain theologians and philosophers. The recent translation of certain of his writings has stimulated wider interest among social scientists.

**Work in social psychology.** Scheler's major contributions to the social sciences lie in the domain of social psychology and the sociology of knowledge. His first major work, *Ressentiment* (1912), contains a comprehensive phenomenological description of this sentiment as well as an attempt to locate the *ressentiment*-laden man within the social structure. He developed the notion that certain social roles—the spinster, the mother-in-law, the priest, for example—predispose their occupants to *ressentiment*, an attitude arising from a sense of impotence in the face of the cumulative repression of feelings of hatred, envy, and desire for revenge. In contrast to Nietzsche, who coined the term, Scheler located the breeding ground of *ressentiment* in the modern bourgeois and post-bourgeois world rather than in Christianity.

In *The Nature of Sympathy* (1913), Scheler presented a detailed description of this feeling state. Here he wedded the phenomenological method to the Pascalian endeavor to outline a "logic of the heart." Scheler attempted to uncover eternal uniformities in feelings and emotions and to show that these, far from being the blind results of mechanistically operating associations, are actually means of knowing which reveal, through their intentionality, the situation of man in the universe and the ethical a priori of a distinct realm of eternal values. As in much of his later work, Scheler defended the thesis that values exist independently of the men who make the evaluations and justified his resolute opposition to all pragmatist, naturalist, or positivist theories of value. Polemics against such philosophical currents, more especially against Kantianism and Neo-Kantianism, form a major part of Scheler's work. His *Formalismus in der Ethik* . . . —first published in 1916 but written before the war (*Gesammelte Werke*, vol. 2)—contains the most elaborate development

of his anti-Kantian polemics as well as ethical speculations and sociological considerations that anticipate many of his later sociological ideas. *On the Eternal in Man* (1921) is the fullest exposition of Scheler's religious thought and also contains germs of his later sociological views.

**The sociology of knowledge.** Scheler's contribution to the sociology of knowledge is to be found in his "Probleme einer Soziologie des Wissens" (1924), two years later expanded in *Die Wissensformen und die Gesellschaft* (*Gesammelte Werke*, vol. 8). He attempted to synthesize a Platonic doctrine of eternal immutability of a world of value essences with a comprehensive relativism. He described how different groups of men have striven, each in its socially and historically limited way, to grasp aspects of the eternal sphere of value essences. The infinite variety of subjective a priori, the fact that different groups, or periods, or individual types elaborate their own forms of knowledge, meant to Scheler that men are striving to attain the value essences in different ways at different times rather than that the immutability of these very essences is limited. *Real factors* (such as biological, political, or economic constellations) favor or oppose the actualization of *ideal factors* (for example, moral, religious, or intellectual values), but they can never determine their content. They can only act as "sluice gates of the spirit." Scheler rejected Comte's "law of three stages" and stressed that religious, metaphysical, and scientific knowledge do not succeed each other in regular progression but rather coexist in every age, rooted though they are in the conditions of life of different groups of men and different human types. Yet Scheler found a grain of truth in Comte's dogmatic assertion that there are stages in human history in the sense that in different periods different substructural elements determine the predominant cultural outlook of the age. At the dawn of history, "blood"—that is, racial and vital factors—chiefly controlled cultural life. After the emergence of the state, political factors moved to the foreground. With the bourgeois age, economic factors have achieved unquestioned predominance. While earlier periods accorded pre-eminence to religious and metaphysical types of knowledge, the bourgeois age is primarily the age of the scientist.

Scheler's world view has a deeply aristocratic cast. The idea of hierarchy is central to it, and the equalitarian tendencies of the modern age were therefore deeply abhorrent to him. His doctrine of moral values is hierarchical: pleasure values, those concerning the pleasant or unpleasant, are inferior to vital values, those promoting well-being and

health, while these are again inferior to spiritual values; the highest values, however, are of a religious or sacred character. To such a hierarchy of values corresponds a hierarchy of men representing them. The saint incarnates the sacred values at the very top of the hierarchy; the genius stands for the spiritual values; the hero stands for the vital values; even in the lowest world, that of pleasure, "artists of consumption" are needed to guide our uncertain taste.

To the hierarchy of values and of men embodying them there corresponds a hierarchy of forms of sociation. The lowest form is the simple horde, in which emotional contagion and unconscious imitation constitute the only bond. In the vital community, on the other hand, in the family or tribe as well as in classes or professions, conscious solidarity binds the participants. As against the horde, the social here prevails over the individual; each member can easily be substituted for any other. In the third type of sociation, Tönnies' *Gesellschaft*, superficial contractual bonds between individuals replace supra-individual goals that are consciously supported. Finally, at the apex of the hierarchy, the *Gesamtperson*, the "complex collective personality," represents a type of sociation in which a quintessential solidarity binds the members in a community of love. This last form, of which the church and the nation are central examples, is eminently superior to all others; within it alone can the higher values be realized.

To posit equality between persons and so to level essential differences of value was, to Scheler, the chief aberration of the modern age. His full-scale attack against the post-Christian world, his rejection of liberalism, altruism, humanitarianism, and democracy can best be understood as resulting from his conviction that the modern world with its leveling tendencies has undermined the objective hierarchy of men and values. His cultural criticism hence proceeds from a profoundly elitist point of view. The modern social scientist will of necessity have to sift Scheler's very real contributions to sociology and social psychology from the antidemocratic ideology in which they are all too often embedded.

## SCHIZOPHRENIA

Schizophrenia constitutes the core problem of insanity. The conditions subsumed under the heading are among the most devastating to which man is heir, blighting him in the process of development or in the prime years of life and commonly leading to his progressive enclosure in an autistic world beset by delusion, hallucination, and fear of involvement with life and people. Because of the diverse manifestations, courses, and outcomes, schizophrenic reactions elude precise definition and concise description. They may be defined as gross failures to achieve or maintain integrated personality functioning in which a person, unable to cope with problems of living and irreconcilable conflicts, withdraws and seeks solutions by breaking through the confines imposed by the culture's ways of thinking and reasoning and by regressing to a period of childhood when reality gave way to fantasy and when the self and others were not yet clearly distinguished. The condition tends to be self-perpetuating because the patient abandons testing his ideas in terms of how they help master his environment and promote collaborative interaction with others. However, restitutive efforts are usually made because a person cannot achieve an equilibrium as an isolate and because fears of uncontrollable impulses interfere with autistic gratification.

**Incidence and prevalence.** Schizophrenia is among the most common conditions leading to profound incapacitation. Of the daily hospital census in the United States of about 1.4 million patients, approximately one-fourth are hospitalized because of schizophrenia. Although the large majority are discharged within the first year after admission, the average length of stay is 13 years because a sizable number remain in hospitals from adolescence or early adulthood until death from old age or some disease. Incidence and prevalence can be estimated only very roughly because of the

number of schizophrenic patients who are never hospitalized or even diagnosed and because of the vague boundaries of the condition. It has been estimated that between 14 and 20 of every 1,000 children born in the United States will be hospitalized at some time in their lives with an illness diagnosed as schizophrenia. A minimum annual prevalence rate of 290 per 100,000 has been suggested for Western societies (Lemkau & Crocetti 1958). Surveys in New Haven (Hollingshead & Redlich 1958) and in England (Brooke 1959) have shown that both incidence and prevalence are much higher among the lower socioeconomic segments of the population than among the upper-middle and upper classes. [See MENTAL DISORDERS, article on EPIDEMIOLOGY.]

## Concepts of schizophrenia

The profound divergencies of opinion concerning the nature, etiology, and treatment of schizophrenic conditions reflect differing concepts of the nature of human adaptation and integration more than they reflect divergent findings. Traditionally, psychiatrists have considered that the profound incapacitations of schizophrenic patients and, particularly, the disordered thinking that forms a critical aspect of the condition must be due to some unknown biological impairment—a structural defect of the brain or some hereditary metabolic or toxic factor influencing cerebral functioning. A large majority continues to believe that the high familial incidence indicates a hereditary predisposition that is affected by environmental factors, perhaps through aggravating a metabolic dysfunction. However, others consider schizophrenic reactions as an extreme type of aberrant personality functioning resulting from faulty and distorting child rearing in deviant family environments.

The way in which schizophrenia is conceptualized is not simply a matter of academic interest but of vital moment, as it influences the direction of scientific investigations and therapeutic efforts and, as will become apparent, has even profoundly influenced the clinical picture and course of the condition. The conviction that schizophrenia is a disease due to a biological impairment leads to concentration of research in neuropathological, physiological, and biochemical fields and has created therapeutic pessimism. This attitude has often contributed to the neglect of patients and, at times, virtually condemned them to crowded and impersonal institutions that aggravated their autistic withdrawal. Such orientation left little room for the participation of social scientists, other than in studies of the economic and social implications

of a devastating disease. In contrast, the conceptualization of schizophrenia as a type of aberrant personality development has made it possible to consider schizophrenic reactions in the study of how the developmental process can go awry and thus perhaps to clarify critical issues concerning human integration and emotional homeostasis. Investigations of such matters as the role of language in human adaptation, of the family as a critical social institution that mediates between biological and cultural directives and between the individual and society, of the influence of social class on the incidence of mental illness and how it relates to child-rearing practices, of cross-cultural influences on personality development, and of the social and political structure of mental hospitals and the society's system of caring for the ill, and numerous other areas of study become a vital part of the effort to understand, control, and treat schizophrenic reactions. Further, as schizophrenia constitutes one of the dominant unsolved health problems, the training of all physicians as well as of psychiatrists in particular will be affected profoundly by the conceptualization of the problems and the projection of an approach to their solution.

**Historical considerations.** The concept of schizophrenia as a clinical entity derives from Emil Kraepelin's recognition in 1896 of the relationship between three forms of insanity—catatonia, described by K. Kahlbaum in 1863; hebephrenia, described by E. Hecker in 1871; and the deteriorating paranoid psychoses—and his uniting them under the designation "dementia praecox," which B. Morel had used for a type of deteriorating adolescent psychosis. Kraepelin brought a degree of order to psychiatric taxonomy by differentiating dementia praecox from the manic-depressive psychoses. He emphasized the progressive course of dementia starting in youth and envisioned a distinct disease entity for which a specific structural pathology or causative agent would be found. The term "schizophrenia" was introduced by Eugen Bleuler in 1911, because not all sufferers from dementia praecox were youthful and not all became demented; it also served to emphasize the splitting of the psychic functions—the intellectual, affective, and conative—in these patients. Bleuler considered the possibility of a psychological causation but favored a hereditary etiology. He considered that the unknown etiologic agent produced primary symptoms of disturbances in associations, abnormalities of affect, emotional and intellectual ambivalence, and turning from reality to fantasy, as well as autism, whereas such symptoms as delusions, hallucinations, motor disorders, etc., were secondary and

amenable to psychological treatment. He also stressed the intact capacities for perception, memory, and intellectual functioning that differentiate schizophrenia from the organic and toxic psychoses. In essence, he outlined the critical paradox of schizophrenic conditions: thought disorders form a critical aspect and diagnostic requisite, but the anatomical and physiological capacities for perceiving, thinking, and remembering remain intact. Together with Carl Gustav Jung, Bleuler brought psychoanalytic insights into the study of the psychology of schizophrenia. [See the *biographies* of BLEULER; JUNG; KRAEPELIN.]

**Adolf Meyer's view.** For the vast majority of psychiatrists throughout the world, the schizophrenic syndrome has remained essentially unchanged since the publication of Bleuler's monograph (1911), although many have adhered more closely to Kraepelin's concepts of a clear-cut disease entity, as the collected papers of the 1957 World Congress devoted to schizophrenia demonstrate (World Congress . . . 1959). However, Adolf Meyer, the dominant American contemporary of Bleuler, did not consider schizophrenia as an illness but as a reaction type that could be brought on by faulty "habit patterns," including habits of thinking and relating (Meyer 1896-1937). For many years Meyer was almost the only important influence advocating longitudinal dynamic studies of life histories of schizophrenic patients, and he countered the prevailing therapeutic pessimism with his melioristic approach which advocated a type of psychotherapeutic management in a socializing milieu. Meyer is largely responsible for the different perspectives concerning schizophrenia held by many American psychiatrists in contrast to those of their Continental colleagues. [See the *biography* of MEYER.]

**Psychoanalysis.** Even though Freud had excluded the treatment of schizophrenia from the province of psychoanalysis because he tacitly accepted an organic or toxic etiology and considered that the regression to narcissism prevented formation of a transference relationship, psychoanalysis still made many major contributions to understanding schizophrenic patients and their symptoms. Such concepts as narcissistic fixation and regression, the psychosexual stages of development, infantile sexuality, the withdrawal of cathexes (libidinal investment) from objects, primary process thinking, the interpretation of dreams, the exposition of the defense mechanisms—particularly those of projection and introjection—and of the importance of homosexuality to paranoid states, etc., opened the way for a dynamic under-

standing of schizophrenic patients and for comprehension of productions that previously had seemed to be the incomprehensible utterances of a diseased mind. Harry Stack Sullivan was among the first analysts who focused attention on the treatment of schizophrenic patients and whose psychoanalytic orientation was greatly modified by work with them. In the process he found need and use for contributions from various behavioral sciences. Sullivan (1924-1933) and his colleague Fromm-Reichmann (1948) were major forces in demonstrating by determined efforts that psychoanalytic therapy could be adapted to the treatment of schizophrenic patients. [See the biography of SULLIVAN.]

### Clinical descriptions

The nature of the disorder varies widely. Most often schizophrenic reactions become manifest in the adolescent or young adult when the impact of sexual drives and the attainment of independence, an identity, and a way of life present critical problems. The young person may gradually and insidiously become increasingly withdrawn, preoccupied, and resistant to direction from others. He may avoid facing problems and relating to others by sleeping through much of the day. Sudden outbursts of irritability or hostility toward family members ward off intrusions. Rumination over personal and philosophical problems increases, and intellectualizations displace commitment and show of emotions. Differentiation from adolescent "identity crises" or other types of adolescent turmoil is difficult, and the future of the youth may hang in the balance. Gradually withdrawal becomes more extreme, indecision paralyzing, and ambivalence of feelings pronounced. Appearance and bodily hygiene may be neglected. Communication becomes vague, missing the mark and leaving the listener puzzled. Feelings of unreality and depersonalization are common. Self-direction is rescinded or paralyzed, allowing drive, impulse, and fantasy to gain increased motivating force. Control of drives and hostilities becomes a major preoccupation, while motivation is sought through interpreting coincidental events and reading meanings into people's expressions and gestures. Then delusional solutions and hallucinated directives are found. Unacceptable feelings and impulses are projected onto others, who become malevolent figures. Hypochondriacal complaints are common and may reflect fears of transformation into the opposite sex. Increasingly the patient lives in an autistic world, gaining a sense of worth or even greatness through fantasy; he is also a prey to delusions of persecution and to terror lest homicidal, suicidal,

or incestuous impulses overwhelm him. In some patients the first serious indication of the psychosis comes in an outbreak of panic over loss of control or over projected dangers. Frequently, when the patient can remain isolated or when he is neglected in an institution, habits and bodily care deteriorate, communications become disorganized and bizarre, and the patient comes to live in a world of delusion and hallucination. He exists in a state of almost living death, a nonparticipant in society and its conventions, virtually beyond the reach of therapeutic intervention. However, such outcomes are not inherent to schizophrenic reactions and need not occur, and with improved treatment they are becoming less common even in large institutions. The course and outcome vary widely and are influenced markedly by the treatment provided. Under average current conditions, approximately two-thirds of hospitalized patients will be discharged within 12 months: about half of these will remain reasonably well, while the remainder will have further serious difficulties and tend to have a downhill course. The outlook is poor for those who cannot be discharged within the first year. However, as less flagrant forms of schizophrenia are now diagnosed more often than formerly and as better treatment opportunities are available to some, the diagnosis need not imply so poor a prognosis. Schizophrenic reactions are most likely to occur in persons who have socialized poorly and who tend to be shy, introspective, somewhat eccentric, and, perhaps, compliantly overconscientious. Still, a fair proportion have not been notably schizoid, and some have been outgoing but impetuous individuals. Lifelong difficulties in socializing and an early progressive withdrawal decrease chances of recovery.

**Types of schizophrenia.** Conventionally, four types of schizophrenia are described. Actually, most patients can be fitted into these types only arbitrarily, showing admixtures of two or more types, with shifts in the dominant symptomatology over time. However, brief outlines of these subgroupings will serve to describe some of the different clinical pictures.

**Catatonic schizophrenia.** In catatonic schizophrenia extremes of violent motor excitement or rigid immobility dominate the picture. Onset is often abrupt. The patient may maintain difficult postures for hours, days, or months and requires complete care. Alternations between extreme excitement and rigidity may occur. Frequently these patients are in the midst of some mystical experience, believing themselves in heaven or hell; they are often immobile and refuse to speak because

they believe any movement or word can produce a universal catastrophe. Although they may appear out of contact, they are aware of and sensitive to their surroundings. The prognosis is more favorable than for other types but unpredictable in the individual case. Chronic catatonic states, once fairly common, are becoming infrequent in modern hospitals.

*Simple schizophrenia.* Simple schizophrenia usually refers to a gradual withdrawal of interest and a progressive decline of responsible behavior with absence of commitment to a definite way of life. The potentialities shown in youth dissipate, and the patient idles about the home or becomes a vagrant, etc. Theoretically, Bleuler's primary symptoms are present with minimal secondary symptoms; however, many patients given this diagnosis are delusional but noncommunicative about their delusions and hallucinations.

*Hebephrenic schizophrenia.* Hebephrenic schizophrenia usually starts in adolescence and progresses rapidly: the patient soon displays silly, impulsive, and disorganized behavior. Delusions and hallucinations are poorly organized and shifting. Speech is often fragmented and almost incomprehensible, marked by frequent intrusions of primary process material.

*Paranoid schizophrenia.* In paranoid schizophrenia delusions of a persecutory type dominate thought and behavior; ideas of reference are common and blend with auditory hallucinations. Megalomaniac delusions relate to ideas of being the focus of widespread plots. The later in life the onset, the more likely it is that the delusions will be systematized and the reaction type approach the condition described under paranoid states. [See PARANOID REACTIONS.]

*Other subcategories.* The current official nomenclature includes a schizoaffective type to cover the numerous patients who display an admixture of schizophrenic and manic-depressive symptoms: if these are considered separate entities, such patients would be suffering from both conditions. However, if schizophrenic reactions are regarded as a type of aberrant development leading to failures of personality integration, other such combined diagnoses will be used. Sociopathic youths can also be more or less schizophrenic; hypochondriacal neuroses may shift to psychoses with somatic or hypochondriacal delusions; obsessive patients can decompensate with obsessive thoughts becoming increasingly bizarre and delusional. Further, although the typical schizophrenic reactions are readily diagnosed, there are no clear boundaries that delimit the use of the diagnosis.

Those who are reluctant to relinquish the concept of schizophrenia as a progressive deteriorating disease seek to distinguish between process and nonprocess schizophrenia or between schizophrenia and schizophreniform conditions (Langfeldt 1933): the patients who recover or who are amenable to psychotherapy, etc., are not considered as true schizophrenics and supposedly can be distinguished by their premorbid behavior, heredity, and symptomatology—a view not widely shared in the United States.

The diagnosis of pseudoneurotic schizophrenia (Hoch & Polatin 1949) is used by some psychiatrists to indicate patients with panneurotic symptomatology who are not amenable to psychotherapy because they are really schizophrenic, but others consider these as "borderline" patients whose neurotic symptoms form a defense against personality disorganization. Borderline schizophrenia refers to patients who maintain a tenuous integration with meager defenses against incursions of primitive impulses and strange primary process material into consciousness.

Childhood schizophrenia refers to cases occurring before adolescence. It is not clear if cases occurring early in childhood are related to the adult condition. Early infantile autism is a puzzling illness that occurs in the first few years of life; the child begins to display peculiar repetitive behavior and regresses, paying little attention to other persons. Some of these children clearly suffer from brain anomalies or brain damage; others have been raised by unempathic, intellectualizing parents. These conditions cannot be discussed adequately in this section. [See MENTAL DISORDERS, article on CHILDHOOD MENTAL DISORDERS.]

The confusions concerning nomenclature have been presented because the various terms are in common usage but also because they reflect the difficulties and ambiguities in the field. Terms may be used in the literature with a certainty that can be misleading, leaving the inexperienced person—and even the experienced one—feeling ignorant rather than perplexed when he cannot make a clear-cut diagnosis.

### Concepts of etiology

*Impairment of brain functioning.* The conviction that such profound personality disorganizations, marked by disordered thinking and often progressing to an almost vegetative state of existence, must reflect impairment of brain functioning has led to intensive investigations of post-mortem and biopsy sections of the brain and of every endocrine, toxic, and biochemical factor that might

conceivably affect cerebral functioning. The erroneous assumption that insulin coma therapy cured schizophrenia led to an upsurge of such studies in the 1930s and 1940s, and currently the meliorating effects of the phenothiazine drugs have provided renewed impetus. Investigators have again and again reported some biochemical factor they consider specific to schizophrenia, and each of these findings has been invalidated sooner or later. A number of these factors have turned out to be related to such things as dietary inadequacies or are concerned with physiological disturbances secondary to chronic emotional disturbances or to prolonged inactivity or some other influence of chronic hospitalization.

*Neuroanatomical investigations.* None of the numerous reports of an abnormality of the brain has been validated. The similarities of the personalities and developmental histories of patients with psychomotor epilepsy and schizophrenia form an interesting lead that is under study.

*Endocrine investigations.* Although the thyroid, pituitary, gonadal, pineal, and adrenal cortical and medullary secretions have all been implicated, no evidence has held up. The intriguing hypothesis that epinephrine undergoes an anomalous breakdown into psychotoxic substances is being pursued (Hoffer 1964), but recent evidence does not bear out the initial enthusiasm.

*Biochemical investigations.* Recently emphasis has been directed to the study of brain amines and indole excretion, and to psychogenic agents such as LSD-25 and the supposedly psychogenic extracts of schizophrenic serum. Various theories relating several such factors have been proposed. Intensive work is advancing knowledge of brain chemistry and fosters hope for future discoveries pertinent to schizophrenia, but recent premature enthusiasms indicate a need for more carefully controlled and validated work before publication. [See MENTAL DISORDERS, *article on BIOLOGICAL ASPECTS.*]

*Genetic hypothesis.* The high familial incidence of schizophrenia had led to virtual acceptance of the belief that some genetically transmitted factor plays an important role in the etiology of schizophrenia [see MENTAL DISORDERS, *article on GENETIC ASPECTS*]. It has been primarily the evidence from twin studies that seemed to demand acceptance of a strong hereditary influence. Until very recently all twin studies reported a much higher concordance rate in identical twins than in same-sexed fraternal twins or siblings—as high as 86 per cent in identical as against 17 per cent in same-sexed fraternal twins. Lately, several investigators

noted puzzling inconsistencies in the data. The only two studies of all twins born within a given span of time rather than of samples of hospitalized patients fail to validate the earlier findings. A survey of all male twins born in Finland between 1930 and 1935 found that none of the 16 schizophrenic patients among the identical twins had a schizophrenic co-twin (Tienari 1963). Studies in Norway of an even larger sample, although still incomplete, indicate that concordance rates for identical twins will not be much higher than for same-sexed siblings (Kringlen 1964). It appears as if the striking results of prior twin studies were due to sampling errors and that this basis for the genetic hypothesis of schizophrenia has been badly shaken.

*Family environment.* A high familial incidence of personality traits or illnesses has often led to erroneous overemphasis of genetic factors. Attention has been directed increasingly to the role of the family environment in producing schizophrenic offspring. Psychoanalytic theory, in considering schizophrenia related to fixations at the oral stage of development, drew attention to failures in the earliest mother-child transactions. As early as 1924, Sullivan emphasized the noxious influence of certain mothers on the development of their schizophrenic sons, both directly and because of their attitudes toward their husbands (1924-1933). Considerable etiologic significance has been given to the "schizophrenogenic mother" who is either aloof, unempathic, and unable to cathect in the child properly or, more typically, cannot establish boundaries between herself and the child, engulfing and controlling a child she needs to complete her life. Studies since 1949 (Lidz et al. 1965) have revealed deficiencies and abnormalities in the total intrafamilial environment. The fathers are frequently just as severely disturbed as the mothers. The family is split by enduring conflict between the parents in which each demolishes the worth of the other to the children, or the family transactions are distorted because one parent acquiesces to the spouse's strange ways of rearing children and patterning the family life. The generation roles within the family are confused in a variety of ways such as parental rivalry with a child or parental dependency upon an immature child, including heterosexual or homosexual incestuous proclivities. Parents fail to adhere to their respective sex-linked roles, either because of homosexual tendencies or through reversing maternal and paternal roles, or because a mother cannot fill an affectional-expressive role or a father an instrumental role. The parent of the same sex as the child who becomes schizophrenic

does not form an adequate model for identification, a situation that is often aggravated because this parent's worth is undercut by the spouse.

Communication within the family is always disturbed and often clearly irrational or paralogical. The intrafamilial culture may deviate markedly from that of the society into which the child must eventually emerge. These families teach or indirectly inculcate irrationality, providing a poor foundation in reality testing and for understanding verbal and nonverbal communications outside of the family. The schizophrenic patient's siblings are almost always seriously affected: more are psychotic than are reasonably well-integrated, and with rare exception their occasional "normality" is achieved at the price of serious constriction of the personality.

The finding that schizophrenic patients always grow up in seriously disturbed families forms the most consistent lead concerning the etiology of schizophrenia. Essentially similar phenomena have been reported by research groups in many different countries. In conceptualizing how such disturbed family transactions can lead to schizophrenia in an offspring, some investigators focus primarily upon how the disturbed patterns of communication foster the schizophrenic thought disorder. The "double bind" hypothesis (Bateson et al. 1956) notes how the patient is habitually caught in a bind because a parent covertly sends conflicting messages that perplex and paralyze, causing him to be rebuffed whichever way he responds; or he is caught between the opposing needs and demands of his two parents, and satisfying either parent provokes rejection by the other. Various other communication problems have been noted: the ways in which the child is taught to deny or ignore what should be obvious; the distortions of meanings to support a parent's tenuous emotional equilibrium; the fostering of distrust in the utility of verbal communications; the teaching of eccentric or delusional beliefs; the blurring of the system of meanings and constructs by inconsistent reinforcement by parents, etc. (Lidz et al. 1965). The amorphous or fragmented nature of the thinking and communicating of one or both parents has been carefully documented (Wynne & Singer 1963). Studies of the family communication patterns clarify why the patient suffers from a thought disorder and how such resultant impairments in thinking and communicating create profound disturbances in ego functioning.

The family disturbances, however, clearly affect the child's development deleteriously in other significant ways. A broader approach to the problem

takes cognizance of how failures of parental nurturance, particularly the mother's difficulties in relating to the child, interfere with the development of adequate autonomy; how the disturbances in the family structure distort the structuring of the child's personality by improper channeling of drives, through confusing child and parent roles, by creating confusions in sexual identity, by impeding proper resolution of the oedipal situation, etc.; as well as of how parents' failure to transmit adequately basic adaptive or instrumental techniques of the culture, including its system of meanings, impairs ego functioning and socializing capacities (Lidz et al. 1965).

The family studies have thus far been largely exploratory, paving the way for the formulation of hypotheses that are now being studied with more rigorous methodology. Although not definitive, they have served to move research concerning the etiology of schizophrenia out of the frustrating whirlpool in which it had been caught. Many puzzling aspects of schizophrenia now seem far more comprehensible. The findings interdigitate with those of other approaches, such as studies of the relationship between social class and incidence of schizophrenia, twin studies, and psychoanalytic concepts of developmental dynamics. The knowledge gained from these studies has also had a marked impact upon therapy, particularly through drawing attention to the need to consider the family as a unit rather than simply to focus upon the individual patient.

## Therapy

Despite the absence of any specific method of treatment, marked changes have taken place in the therapy of schizophrenic patients since 1940. Perhaps the most important change has been the gradual but progressive abandonment of the defeatist attitude concerning schizophrenia that had pervaded most of psychiatry since the mid-nineteenth century. Although debates have waged concerning the value of insulin coma, electroshock, frontal lobotomy, milieu therapy, and various forms of individual and group psychotherapy, psychiatrists and other personnel finding something they could do or try to do became interested in the patients, and the patients responded. It became apparent to increasing numbers of psychiatrists that schizophrenic patients need not follow a downhill course, and that many of the extreme manifestations were products of neglect and virtual abandonment in impersonal institutions. The enormity of the problem of caring for and attempting to treat the masses of institutionalized patients

has been overwhelming, and adequate treatment for any other than selected patients has had to await reorganizations of hospital systems and the training of the necessary personnel.

Therapeutic efforts must be suited to the patient, the facilities available, and the therapist's abilities. Whereas the prognosis for schizophrenic reactions collectively is generally discouraging, the outlook for the individual patient, particularly if treatment begins soon after symptoms appear and intensive care can be provided, may be regarded hopefully.

**"Organic" treatments.** Although insulin coma therapy, introduced in 1933, did much to revive interest in the treatment of schizophrenic patients, it has now been virtually discarded, its apparent efficacy having resulted from the increased attention to patients it required. Electric convulsive treatments are of occasional value as a means of quieting extremely excited patients. Various tranquilizing drugs, particularly the phenothiazines, have largely replaced other "organic" treatments. The phenothiazines serve to lessen anxiety and agitation and probably diminish distraction by extraneous stimuli and primary process intrusions. Trifluoperazine may be particularly useful in diminishing hallucinations. An array of psychotropic drugs is now available, and opinions differ as to the merits of each. Properly controlled experiments on the relative worth of these medications are extremely difficult to conduct. It seems reasonably certain that many patients can return to or remain in the community largely because of these agents. A major influence of tranquilizing drugs has been indirect; they have helped quiet the wards in mental institutions and provided a means of controlling seriously disturbed patients. This has helped produce great changes in mental hospitals through unlocking doors, permitting patients greater freedom, and allowing the staff time and opportunity to improve the therapeutic milieu. [See MENTAL DISORDERS, TREATMENT OF, article on SOMATIC TREATMENT.]

**Milieu therapy.** Establishing a suitable therapeutic hospital milieu has altered the prognosis for schizophrenic patients as much as the tranquilizing drugs, but in all except certain select institutions, reorganization had to await the quieting effects of the shock therapies and then the tranquilizers. Milieu therapy seeks to counter schizophrenic patients' tendencies to withdraw; it also fosters socialization, promotes responsibility, and provides retraining in interpersonal relationships. The therapy includes a gamut of measures ranging from discarding restraints; minimizing isolation; giving attentive care and interest; fostering socializing, edu-

cational, and occupational activities; and providing group therapy to holding patient-staff meetings and setting up patient government to provide channels of communication and to encourage responsibility for the self and others. Opening the doors of hospitals has a salutary influence and can markedly change the attitudes of both patients and staff, but some patients who are afraid of their impulsivity, aggressions, or suicidal tendencies feel more secure and can socialize more readily when protected within a limited area until they are ready to assume responsibility for their actions.

As schizophrenic patients tend to regress, withdraw, and become passively dependent in institutions, there has been a movement to return such patients to the community as soon as feasible or to attempt to keep them out of hospitals altogether. On the other hand, efforts are often made to promote early hospitalization, for the chances of recovery are greater if treatment starts before symptoms become well established and if the patient can be removed from a pathogenic environment. The paradox revolves around the nature of the treatment a hospital can offer; optimally a hospital should be able to counter regressive tendencies. As yet, relatively few institutions can provide intensive care and treatment that seeks to promote essential personality change rather than mere remission from a psychotic state.

**Psychotherapy.** Establishing a relationship to another person often—perhaps always—provides the impetus and forms the bridge for the schizophrenic patient's return from psychotic withdrawal. The crux of the initial phases of psychotherapeutic work with these patients is the therapist's use of himself to gain the patient's trust and willingness to risk relating again despite the shattering disillusionments of the past. A persistent warm and honest interest by an untrained person may suffice and succeed where a highly trained but intellectualized and uncommitted therapist fails. Schizophrenic patients are usually highly sensitive to pretense, to being used by another person, and to another person's withdrawal in the face of their intense needs or their hostilities. Usually, however, considerable skill and understanding of schizophrenic patients are required. Trust follows upon understanding, understanding requires communication, and the therapist faces the task of establishing communication across barriers imposed by the patient's idiosyncratic language usage, his personalized metaphor, his efforts to conceal and yet convey, the delusions and hallucinatory interruptions, and the projections of the patient's thoughts and feelings onto the therapist, etc. The therapist

must be prepared and able to counter or weather the patient's flights into withdrawal, particularly when the patient feels on the verge of trusting and becoming involved—setbacks that test the therapist's commitment. Bringing a patient out of his psychotic regression and withdrawal can be a very real and rewarding achievement, but something that often occurs without specific psychotherapy; the process is more successful when the therapist is a focal point in a proper therapeutic milieu that counters the patient's regression in many ways than when the emphasis is solely upon the individual psychotherapy.

Psychotherapy of schizophrenia usually implies more than bringing the patient out of the psychotic episode or into socially acceptable behavior. It often involves the effort to promote profound personality changes through psychoanalytically oriented interpersonal transactions. Such work with schizophrenic patients differs markedly from the analysis of psychoneurotic patients. It seeks to strengthen ego functioning through fostering a more cohesive identity, firmer boundaries between the self and others, and control of primitive impulses. Treatment almost always includes extensive re-evaluation of parental figures and efforts to modify the sway of sabotaging parental introjects. The intense nature of the transference relationship once it is established, together with the fragility of the relationship, places great demands upon the therapist. It is a task for highly skilled therapists with specific experience and training in the field and will not be discussed here. The effectiveness of intensive psychotherapy with schizophrenic patients cannot be evaluated in statistical terms: the belief in its value derives from the excellent results obtained with a number of individuals and from the meaningfulness of the material gained in the process. Much depends on the specific therapist as well as on the specific patient. The aims of such work are directed in part toward the future—to increasing knowledge and improving techniques. [See CLINICAL PSYCHOLOGY; MENTAL DISORDERS, TREATMENT OF, especially the article on PSYCHOLOGICAL TREATMENT; PSYCHIATRY.]

**Family therapy.** Recent advances in understanding of the pathology in the schizophrenic's family of origin have brought the family into the therapeutic efforts in a variety of ways. Social workers or psychiatrists have worked with parents individually or in groups to allay their anxiety and guilt; to counter the common tendency of parents to interfere with or disrupt the patient's therapy; to modify the parents' attitudes toward each other as well as toward the patient; and to foster more

direct and forthright communication. With some families a major effort is made to prevent exclusion of a hospitalized patient and withdrawal of interest in him and in others to help prevent disintegration of the family after the patient has been hospitalized. Conjoint family therapy in which parents and patient or the entire family are seen in group sessions has been found advantageous. The therapist has an opportunity to view directly the nature of the disturbed relationships and communications; the patient may gain a new perception of his parents and an appreciation of their limitations and idiosyncrasies; and other family members may recognize their own roles in provoking or continuing the patient's illness, gain insights concerning the family transactions, and begin to relate differently. Although some psychiatrists consider conjoint family therapy to be the optimal treatment procedure, others use it as an important adjunct to alternative therapeutic measures.

### Perspective

The disagreements between virtually all schools of psychiatry concerning the nature and etiology of schizophrenia have interfered with the presentation of a coherent and cohesive approach to the problem. Although schizophrenia is traditionally considered a disease of unknown etiology, a great deal is now known about the developmental problems and the dynamic psychopathology of these patients and about the family environments that tend to produce them. Man is unique in the degree that his adaptation rests on a lengthy period of dependency upon parental figures during which he must assimilate the instrumental techniques of his culture to implement his inborn adaptive capacities. There are countless chances for misdirection, confusion, and conflict to arise in the process. The very mechanism that permits his inordinate adaptability contains a major vulnerability. He depends upon language and a coherent way of thinking to guide him into the future and on an ability to communicate to enable collaborative interaction. Yet linguistic meanings and a system of logic are not inborn but acquired as a means of problem solving by communication with others and by sorting out life experiences. How correctly meanings are learned and how firmly they become ingrained depend largely on the parental tutors—the consistency of their communications as an aid to problem solving and the emotional relationships between parents and child. There are countless ways in which the enculturation process can go wrong. When a person is caught in insoluble conflicts, when a path into the future is barred, when

even regression serves little because the persons upon whom one could depend are distrusted or feared, there is still a way. One can alter the perception of his own needs and motives and those of others. One can abandon causal logic, change his internal representation of events, retreat to a period of childhood when reality gave way to fantasy, and cut off movement toward a realistic future; that is, one can become schizophrenic. This path is so clearly open to man, particularly to those who have had confused or confusing guides to follow into adulthood and have received poor foundations in meaning systems and reality testing, or who have actually been trained to irrational ways in childhood, that conditions such as schizophrenia must be expected as anomalies of the human developmental process. The acceptance of such a theory that schizophrenic reactions result from anomalous socialization processes and that the family forms the primary enculturating agency provides numerous guides for research and therapy, and it directs the psychiatrist toward increased collaboration with behavioral scientists.

### SCHLESINGER, KARL

Karl Schlesinger (1889-1938) was born in Budapest and died in Vienna, committing suicide on the day Hitler took possession of that city. (He had moved there after Béla Kun's 1919 communist revolution in Hungary.) A wealthy financier and a member of many industrial and financial boards, Schlesinger was one of the very few important contemporary theoretical economists who was not part of the academic world; he never held an academic post but was an active and highly respected member of the Vienna Economic Society. Although his contributions to economics were greatly appreciated in Vienna, his important early work of 1914, *Theorie der Geld- und Kreditwirtschaft* (see 1914a), was not readily available at the time he moved there; its direct influence upon Viennese monetary theory was less than might have been expected.

In his 1914 book Schlesinger made extensive use of some simple mathematics, uncommon at that time in German economic writing, particularly in the field of monetary theory. His interest in mathematics led him to take instruction from A. Wald in the 1930s; he eventually proposed to Wald a problem relating to Walras' production equations. This problem concerned Schlesinger's modification of the Walras-Cassel system of production equations by introducing the notion that *all* factors of production—not only the scarce ones—have to be considered and that whether a factor is scarce or free depends on the demand functions. This led to Wald's famous work on the determinacy of the Walrasian system. [See ECONOMIC EQUILIBRIUM.] (Schlesinger acknowledged that Zeuthen had earlier

suggested a similar modification without, however, following up the matter.) These problems were discussed in Karl Menger's mathematical colloquium under Menger's continuing and stimulating guidance. Schlesinger also contributed to Menger's work on the theory of returns.

Schlesinger's *Theorie der Geld- und Kreditwirtschaft* made him the only immediate follower of Walras, other than Wicksell, to advance Walras' theory of money. Schlesinger stressed that in addition to the indirect utility of money derived from its ability ultimately to provide desired consumers' goods, cash balances also have a direct utility. He introduced a probabilistic approach to monetary theory by distinguishing between fixed and uncertain future due dates for payments; the former offer no choice, while the latter permit the individual to maximize utility by choosing appropriately between holding cash and purchasing goods. He further showed that if the number of transactions increases, it is possible to economize in the relative size of cash balances, although this will not be the case if only the magnitude of transactions increases. Schlesinger derived an excess demand equation for money that is virtually identical with the one commonly ascribed to Keynes. [See MONEY.] He also was probably the first to develop the notion of the equilibrium rate of interest [see INTEREST].

Schlesinger was one of the first economists to expound the purchasing power parity theory. In his pamphlet on the variations in the value of money (1916), he stated the theorem that the parity of a country's currency is determined by the quotient of the domestic and foreign general price levels. The equilibrium rate of exchange can only be changed if foreign borrowings are used to reduce the indebtedness of the bank of issue.

In 1931 Schlesinger published a lengthy review of F. Somary's *Bankpolitik* (see 1931a), in which he presented a detailed mathematical analysis of the theory of credit creation by commercial banks, incorporating this theory into the general process of circulation. Assuming there are  $n$  equal banks, that deposits require some cash reserve, and that each individual pays partly in cash and partly by check, Schlesinger analyzed the effects of introducing new metal or new bank notes into the system. He traced the path that credit expansion follows until equilibrium is reached and derived formulas for debtors, creditors, and the system as a whole. He also considered the flow of checks back to their starting point. Several of his restrictive assumptions can be relaxed, but the whole approach is an early model for careful, rigorous analysis of monetary operations. [See BANKING.]

During the international financial crisis of the 1930s Schlesinger proposed that the Austrian government control capital movements, but he was strictly opposed to exchange control as then practiced.

Schlesinger's most significant contributions were to monetary theory, but this work was widely neglected, which caused Schumpeter to comment that "in our field first-class performance is neither a necessary nor a sufficient condition for success" (1954, p. 1082, note 5). More recently, however, he has been given more credit, especially by V. Wagner and D. Patinkin. In addition to his analytical contributions to the numerous discussions about capital theory, business cycles, and general equilibrium theory conducted among economists in Vienna—frequently at odd hours in coffee houses—Schlesinger had important economic insights in which his great experience as a financier and administrator provided a valuable counterweight to his theoretical analysis. Thus, his considerable influence on Viennese economics was far greater than his few publications might indicate.

#### SCHLICK, MORITZ

Friedrich Albert Moritz Schlick (1882–1936), philosopher and epistemologist was born in Berlin. He studied physics at Heidelberg and Lausanne and took his doctorate at Berlin under Max Planck with a dissertation on the physics of light. He then qualified himself for an academic post in philosophy and taught first at Rostock, then Kiel, and finally at Vienna from 1922 to 1936, where he occupied the chair in the philosophy of the inductive sciences, held earlier by Ernst Mach and Ludwig Boltzmann. Schlick became the leading figure of the so-called Vienna circle—a group of thinkers concerned with developing a scientific philosophy in opposition to the prevailing metaphysical orientation of German philosophical thought.

After a brief but highly productive period this school was disrupted and scattered, first by Schlick's death on June 22, 1936 (he was murdered by a mentally disturbed former student), and then by the Nazi invasion of Austria in 1938. However, its influence continued and was strongly felt for another two decades, especially in English-speaking countries (where it became known as logical positivism), as a consequence of the emigration of some of its leading members and sympathizers, among them Rudolf Carnap, Hans Reichenbach, and the somewhat less closely connected Karl Popper.

Although trained as a physicist and strongly motivated by the desire to bring philosophical clarity to the knowledge of nature and to render philosophy more scientific in method and results, Schlick was sensitive to the whole range of problems of knowledge, human existence, and values. He had a simple, clear style free of all technical jargon, rising on occasion to something like the level of poetry.

His first book, *Lebensweisheit* (1908; "Wisdom of Life"), as the name indicates, was devoted to nonscientific issues, as was his last, *Problems of Ethics* (1930a), which, while largely an attempt to give an account of ethics from the causal-explanatory point of view, contains many profound observations on life and values. Aside from these two books and a small separately published essay on the meaning of life, *Vom Sinn des Lebens* (1927), Schlick's contributions to philosophy fall in the fields of the philosophy of science and epistemology.

He did not, however, concern himself with the philosophy of the social sciences; at least he published nothing dealing directly with its special problems (however, see *Natur und Kultur*). The most important of his ideas pertaining to this area are those that are contained in his ethical writings mentioned above. A few words will be said about them before we turn to his principal contributions dealing with knowledge as such.

### Moral philosophy

Schlick distinguished sharply between cognition and experience. Reality is given to us in experience, but that experience is not itself knowledge. This distinction, between *Erlebnis* and *Erkenntnis* ("experience" and "cognition"), which plays so fundamental a role in his theory of knowledge, is no less important in his ethics and *Lebensphilosophie*. Thus, the moral philosopher seeks only to understand moral phenomena, moral conduct—not to guide or create them. The moralist, wise man, or prophet, on the other hand, is interested in the quality of life itself, seeks to enlighten men with respect to the good life, and thus has a practical, not theoretical, goal.

As a moralist, Schlick taught that the good life is the life full, to the highest degree, of activity valued for its own sake. Activities valued in and for themselves are properly called play, and Schlick agreed with Schiller that man is truly man only when he plays. And, as youth is characteristically the time of play, the concept of "youth" is the clue to the meaning of life. Whenever man acts out of the joy in acting, apart from considerations of ends to be achieved, then he is, regardless of his age, youthful in the philosophical sense, and then his life is meaningful. "If we need a rule for life let it be: 'Preserve the spirit of youth!', for it is the meaning of life" (1927, p. 354).

As a moral philosopher, Schlick viewed his task as that of explaining moral conduct, i.e., how it comes about that man does what is required of him by society, which is the moral lawgiver making demands upon him to act, even when such conformance might seem contrary to his own desires. Normative ethics—defining "the good," "what ought to be"—he considered as at most a preliminary to ethics. It is not the task or privilege of the moral philosopher to decide what society ought to mean by these terms but only to ascertain what it does mean. But this does not imply that the philosopher docilely accepts as good whatever society holds to be such; his task is to understand and explain norms, not to accept or reject them. Schlick's view was that society deems and calls good that which

it supposes is beneficial to it—i.e., makes for its happiness—and it demands that its members act accordingly. The ultimate ethical norms, if such there be, are facts in human experience and, precisely because they are ultimate, they neither need nor admit of justification—a senseless requirement but one all too frequently made in the history of ethical thought. Schlick wrote that "even if ethics were a normative science it would not cease because of this to be a science of facts . . ." ([1930a] 1939, p. 21).

According to Schlick, in a situation of choice a man selects that goal the idea of which at the time of choice is relatively more pleasure-tinged or less tinged with unpleasant feeling than the alternatives. Thus men can, and often do, knowingly choose goals that are in their realization unpleasant. In the long run, however, the motive pleasure is in turn affected by the realization pleasure in such a way that goals regularly found to be unpleasant upon achievement, whether because of their own nature or because of social sanctions, cease to be attractive. The combined effect of man's natural sympathy and of social sanctions is to make man identify his own happiness with that of his fellow men. Thus arises that close connection between virtue (moral conduct, i.e., altruism) and happiness, which explains why men act morally.

Of possible interest to students of society is Schlick's analysis of the concept of "responsibility," which he thought should replace the traditional concept of so-called freedom of the will, a concept that in his view is irrelevant to ethics and based on a series of confusions, namely, between causality (determinism) and compulsion, indeterminism (chance) and freedom. That a man's actions are determined means only that they are predictable, not that they are coerced. "Compulsion" occurs where a man is prevented from realizing his natural desires. How could the rule according to which these natural desires arise itself be considered as 'compulsion'?" (*ibid.*, p. 148). Morality and society are both concerned only with who is responsible for the acts they wish to discourage or encourage, and this influence would be impossible if acts were free in the sense of undetermined, i.e., uncaused.

### Philosophy of science and epistemology

Schlick's work in the theory of knowledge and the philosophy of science dominated his scholarly career. It falls into two periods: one culminating in the publication of his chief work, *Allgemeine Erkenntnislehre* (1918), and another beginning with his move to Vienna in 1922 and ending with his death in 1936.

**Experience and knowledge.** The most important single idea of *Allgemeine Erkenntnislehre* is that the experience of something (*Erlebnis*) is not the same as the knowledge of it (*Erkenntnis*). To know something is basically to recognize it, i.e., to find in it something already familiar. Schlick frequently made use of the pair of German terms *kennen* and *erkennen* to make this distinction; the former refers to being acquainted with something, the latter to recognizing it as an instance of something else. This recognition ranges from the simplest cases, such as finding a shade to be a certain color, to recognizing in the phenomena of light something governed (described) by the same laws as those governing electrical phenomena. The whole goal of knowledge as *theory* is to achieve conceptual unification, to discover identity amid diversity. This is a joy in itself, but in addition it gives man the power to master endlessly diverse phenomena with a minimum of basic concepts.

Knowledge is correct description, a true statement or judgment. Contrary to the teaching of Kant, our knowledge is not confined to the realm of phenomena, what is sensibly given, but reaches over into the realm of "things-in-themselves," if by this term we refer to what is not phenomenon, not given in experience. For we can make true judgments about what we do not and cannot experience, as well as about what we can. Knowledge is symbolic, not intuitive.

Such things-in-themselves are defined not in terms of experienced "content" but implicitly, in terms of their relational properties. To know something about such things is not to intuit their qualities but to be acquainted with the laws that describe their behavior. To be real is not to be simply an object of sensible intuition but rather to occupy a position in time. The moment it is shown that for any object the rules of some particular scientific discipline force us to grant it a definite time and place, its real existence is assured. Thus, the existence and nature of atoms, of fields of force, or of the experiences of other persons are vouched for by the laws that describe them correctly, enabling us to predict and control, not by their entering qualitatively into our experience. Physical space and time are not identical with their sensible (subjective) correlates (visual space is not Euclidean) but are known through the laws that describe them.

Considerations of a similar nature were used by Schlick in his polemic against the phenomenalism and "positivism" of such thinkers as Hume, Avenarius, and Mach, whose doctrines he called the "immanence idea" and subjected to sustained and effective criticism.

**Analysis and verification.** Under the influence of Wittgenstein, with whom he was in close personal contact during his Vienna period, certain aspects of Schlick's thought underwent a gradual but appreciable shift of emphasis. Wittgenstein's conception of philosophy as the *activity* of clarifying meaning furnished Schlick with a clearer line of demarcation between philosophy and science, or positive knowledge: the former clarifies concepts and analyzes the meaning of statements, determining their experiential truth conditions; the latter seeks to verify them, determine their truth values. Philosophical activity constitutes the necessary precondition of science but does not itself put forth doctrines, does not take the form of a body of knowledge. It consists rather in those sometimes verbal acts by means of which meanings are "shown." The ultimate meanings of words and statements must be found in what is given in experience, in content.

The great error of metaphysics has been the effort to express the inexpressible, the content of experience. Here again appears the main theme that knowledge is not mere awareness of the given but concerns its form or structure, which alone is capable of being expressed and communicated. Knowledge describes the *relations* which hold between the elements of content, their structure, and specifically, the laws connecting them.

The meaning of a proposition is given by describing the experiential conditions under which it will be true and those under which it will be false, i.e., the conditions in the given that verify and falsify it. This meaning principle, the verifiability principle, plays the dominant role in the philosophical writings of Schlick's final period. Since all meaningful statements must be verifiable and falsifiable in the given, there are no limits to knowledge, for what transcends possible ascertainment does so by transcending significance itself.

It does not follow from the verifiability that only the given exists. This doctrine is itself senseless, as is the opposite view that the given is unreal, mere appearance. "To be real always means to stand in a definite relationship to the given" ([1932] 1959, p. 99). It is in the given that we verify or falsify (strictly, confirm or disconfirm) statements about existence and reality by inferring, from the hypothesis that something exists, that certain experiences will be forthcoming consequent on certain tests or operations and then testing for the truth of these predictions. The laws on the basis of which we make these predictions are the true objects of science. "The subject matter of physics is *not* sensations but laws. The formulation, used by some positivists, that bodies are only

'complexes of sensations' is therefore to be rejected. What is correct is only that propositions concerning bodies are transformable into equivalent propositions concerning the occurrence of sensations in accordance with laws" (*ibid.*, p. 107).

Schlick, in keeping with his nontechnical manner of writing, did not always give very precise formulation to the verifiability principle. In general he distinguished between analytic (logical, necessary) and synthetic (empirical, contingent) statements. Only the latter, and not all of them, are propositions in the fullest sense of being verifiable and falsifiable. Analytic statements are limiting cases, necessary truths, not expressing possible states of the world but definitional, "grammatical" decisions or rules. The logical is the purely formal, the *a priori*; that there are no synthetic *a priori* truths is a central theme of his polemic against Kant and a view common to the school as a whole.

Statements of laws—general hypotheses—not being strictly verifiable, are not genuine, full-fledged propositions but are treated as rules for making predictions, thus as heuristic principles. Since they are not even theoretically verifiable, the question constituting the problem of induction cannot arise, for laws are not propositions (true or false) whose truth values might be inferred from others. Induction is but a methodical kind of guessing about useful rules.

The question of whether determinism is true, whether *all* events are related to others by regularities expressible in laws, is to be distinguished from the question of the nature of causality. The statement that determinism is true is not verifiable or falsifiable and hence is not a genuine proposition. As a guiding principle, however, determinism might be expressed by the precept "Seek causal laws!" A causal law is a formula enabling us to make successful predictions, given certain data. That it holds necessarily (universally), i.e., that determinism is true within a given domain, cannot be *finally* established or refuted, but we can find good empirical grounds for accepting or rejecting the view in particular cases.

Despite his stress on verifiability and falsifiability, Schlick in fact considered all propositions formulated in daily life and science to be hypotheses, at best confirmable or disconfirmable but not strictly verifiable—at least from the point of view of ascertainment, if not of logical theory. The only contingent statements whose truth can be, in the strict sense, established are those that, on the moment of their utterance, report or announce the given (a here-now-thus) in experience. These confirmations (*Konstatierungen*, as he called them) consti-

tute the ultimate connections between language and the world, "the unshakeable point of contact between knowledge and reality" ([1934] 1959, p. 226). All testing of other propositions is in terms of the data constituting the referents of these *basic* propositions, which immediately cease to have meaning when they lose contact with these referents. The propositions actually made use of in science and daily life are "a means of finding one's way among the facts; of arriving at the joy of confirmation . . ." (*ibid.*, p. 226). The pragmatic nature of Schlick's concepts of knowledge and propositions is thus evident.

**Limits of knowledge.** Since knowledge is of laws describing events and since content is incommunicable and cannot be expressed in propositions, we can know the nature of things only in terms of the laws that apply to them, laws that enable us to make successful predictions in the manner described above. The age-old problem of the relation of mind and body finds its solution here. Mind or, better, the mental is what obeys the qualitative laws of psychology; body, matter, or the physical is what obeys the quantitative laws of physics, which, in contrast to the (nonbehavioristic) laws of psychology, are intersensual and intersubjective. The problem of the connection of mind and body is thus the problem of the connection of the *languages* of psychology and physics.

The as yet unestablished but not implausible hypothesis of *physicalism* (materialism freed of its metaphysical connotations) is that the qualitative aspects of experience (content) are correlated with certain physical, quantitative, measurable properties in such a way that from determination of the latter (brain states, nerve impulses, etc.) universally correct inferences could be made to the former; and in general that a complete description of the world can be made on the basis of physical concepts. If this should be correct, then the mental would be explained by the physical, would in a certain sense *be* the physical. That this is so we do not know, but the problem is insoluble and senseless if it requires explaining how extended substance, i.e., traditional "body," can interact with unextended substance—"mind." The mental is in any case often extended, for example, a pain can be spread over an area or occupy a place; hence the traditional problem disappears, to be replaced by one concerning the empirically determinable relation between certain kinds of propositions, not kinds of substances. And if solved, it will be solved by scientific experimentation and discovery, not by "philosophical" or metaphysical considerations.

The reworking of his central ideas in the manner just illustrated—on the basis of his conception

of knowledge as symbolic, essentially concerned with communication and expression, and of expression as dealing with form, not content—was the task that confronted Schlick when he was cut down so tragically in the prime of life.

#### SCHMIDT, WILHELM

Wilhelm Schmidt was born in 1868 in Hörde, Westphalia, and died in 1954 in Fribourg, Switzerland. He joined the Divine Word Missionaries (*Societas Verbi Divini*, or S.V.D.) in 1883 and

was ordained a priest in 1892. From 1893 to 1895 he studied at the University of Berlin, majoring in Oriental languages; he was appointed professor in the St. Gabriel Mission Seminary at Mödling, near Vienna, in 1895 and remained there until 1938. He also taught at the University of Vienna, beginning in 1921, and after he left Austria, he taught at the University of Fribourg from 1939 to 1951. He founded the periodical *Anthropos* in 1906, was director of the Museo Missionario-Etnológico Lateranense in Rome from 1927 to 1939, and was director of the Anthropos Institut at St. Augustin near Bonn from 1932 to 1950.

Early in his career, Schmidt was very interested in linguistic studies, but later he turned increasingly to studies in ethnology and the science of religion. The impetus to his work in these latter fields came from his philosophical, theological, and linguistic training and from the observations made by S.V.D. missionaries, especially in New Guinea and Togo. He was influenced as well by the folklorist Andrew Lang, by the Indologist Leopold von Schröder, and by the ethnologists Friedrich Ratzel, Leo Frobenius, Ernst Grosse, C. N. Starcke, Alfred Vierkandt, Edward Westermarck, Franz Boas, and, above all, by Fritz Graebner and his theories of *Kulturkreise*.

In his studies of the evolution and forms of the family, Schmidt followed Grosse in correlating family types with economic activities. He refined Graebner's theory of *Kulturkreise*, which differentiated between matrilineal and patrilineal societies, seeking to explain their origins on the basis of subsistence patterns; thus, food planters would be matrilineal in descent and residency rules, while nomads would be patrilineal.

He agreed with others, such as Havelock Ellis and Westermarck, in offering psychological explanations for exogamy. Also, his arrangements of traits in *Kulturkreise* are frequently in accord with functionalist ideas (although he did not want to be associated with "functionalism"—see 1944 for his violent criticism of functionalism). Thus totemism is identified with clan exogamy, in contrast with the consanguineal basis of local exogamy; education is linked to initiation ceremonies, which are usually obligatory for all the young men of the tribe, rather than to secret societies, which often constitute an elite and have special requirements for admission.

Schmidt was concerned with the variability of individuals and their relationship to society. He asserted that the individual, even among primitives, exerts an influence on the institutions of his community.

In his 12-volume work, *Der Ursprung der Gottes-*

*idee* (1912–1955), he made use of extensive material supporting the theory that the Supreme Being occupied a position so superior (compared with spirits and other beings of religious significance) in the religion of primitive hunters and gatherers that this religion may properly be considered monotheistic. Subsequently, such monotheism persisted especially in nomadic pastoral civilizations, while in the *Kulturkreise* of the matrilineal agricultural peoples and the more advanced totemic hunting cultures, the figure of the Supreme Being was stifled or supplanted by other religious elements, e.g., fertility cults, ancestor worship, magic. Totemism itself was regarded by Schmidt as essentially social; he particularly stressed its significance for clan exogamy. Although totemism does imply a certain reverence for the totem animal, Schmidt did not consider it a religious phenomenon—an actual animal cult.

From the time that Schmidt became familiar with Graebner's concept of *Kulturkreise* (Graebner believed that he established such *Kulturkreise* for Oceania, including Australia), this concept exerted an influence on his linguistic work. He tried to show that when Australian languages are classified, different groups coincide with totemistic and matrilineal cultures respectively. Furthermore, he attributed certain linguistic phenomena to economic and social change; thus, he felt that the change to uxorial residence and the ownership of land by women might result in the learning of a foreign tongue by the men, and thus contribute to the disintegration of the language. Indeed, Schmidt made an even more comprehensive attempt to relate all aspects of linguistic evolution to general cultural evolution, to explain the former largely in terms of the latter, and to set up parallels between linguistic areas and *Kulturkreise*.

Schmidt's influence was far-reaching, especially in the German- and English-speaking regions of the world, where his journal *Anthropos* was a repository of field data collected by missionaries around the world. Schmidt was also concerned that his findings have a practical application to colonial policy and missionary practice. Many of his publications, especially those dealing with family and social ethics, were addressed to a public wider than the academic one.

## SCHMITT, CARL

Carl Schmitt, German political theorist, was born in 1888 in Plettenberg in Westphalia. He studied law and obtained his habilitation for public law at Strasbourg in 1916. His subsequent academic career was a successful one: he taught at Greifswald from 1921 to 1922; at Bonn from 1922 to 1928; at Berlin from 1928 until early in 1933, at Cologne during the year 1933, and again at Berlin, from the beginning of the academic year 1933/1934 until 1945.

Schmitt is an important representative of a school of thought in German public law which, after World War I, turned away from the German tradition of legal positivism and tried to broaden the scientific study of law and legal institutions by introducing into it historical, sociological, and political considerations. Accordingly, his publications cover a wide variety of subjects: the relationship between written law and judicial decision making, the romantic movement in political thinking during the early nineteenth century, and the history of dictatorship as a political idea and as an institution. He developed a systematic theory of constitutional law and made the history of European public law an object of philosophical investigation. He studied particular issues of constitutional, international, and martial law, and he engaged in polemics over the actual political situation in Germany.

Schmitt's participation in the antiliberal intellectual and political movement in Germany did not preclude his making significant contributions to political science. Observing the importance of arbitrary decisions both in the process of adjudication and in systematic jurisprudence, he established the concept of *Dezisionismus* to designate the fact that any legal order is ultimately based on sovereign decisions. These decisions are based not on positive norms but on the *ultima ratio* of emergency

decrees [see POLITICAL JUSTICE]. Schmitt traced this philosophy back to Hobbes's doctrine that *auctoritas non veritas facit legem* (laws are based on authority rather than truth), as well as to what he called the political theology of de Maistre, Bonald, Donoso Cortes, and other counterrevolutionary thinkers. Schmitt believed that the decisionistic method of looking for extreme and critical cases would lead to a new concrete way of thinking about the political order and political action (*konkretes Ordnungs- und Gestaltungsdenken*). However, the decisionistic method became more than an approach to political phenomena: Schmitt's preoccupation with the "extreme cases," as well as with the counterrevolutionary thinkers' pessimistic view of man, led him to convert the decisionistic method into a moral interpretation of politics and history that, in the turbulent situation in German politics between the two world wars, was to serve as a political ideology.

Schmitt defined politics as emerging from the friend-foe constellations that challenge the polity to distinguish between allies and enemies; friend-foe constellations arise in the situations in which civil war or war between states has to be considered an immediate possibility. All human groups, whether of economic, religious, or ethnic origin, may enter into extreme conflicts. The state, therefore, is valued because it is the institution which protects its citizens against the enemy within and without. Schmitt considered this defensive and repressive function of the state to be the precondition and the guarantee of all law and order in human affairs. He interpreted the modern history of continental Europe as a development from the absolute state of the eighteenth century, through the neutral state of the nineteenth, to the total state of the twentieth [see TOTALITARIANISM]. This total state would overcome the neutralization of political power and the cleavage between the state and society that had resulted from nineteenth-century liberalism. Liberalism and democracy were, in Schmitt's view, incompatible political principles, and the institutions of parliamentary government, once based on genuine political discussion and on the efficient functioning of public opinion, had, in twentieth-century mass society, lost their *raison d'être* and their legitimacy.

The Weimar Republic was, according to Schmitt, a distorted version of what he called a *parlamentarischer Gesetzgebungsstaat*, a distortion which he attributed to the waning of the nation's political homogeneity, which he considered to be caused in turn by the anarchical pluralism of incompatible political forces. Schmitt did not believe that Germany under the Weimar Republic could become

politically integrated. He therefore defended the National Socialists' seizure of power as a way of regaining the authority necessary to restore substantive justice. Thus he provided the ideological justification of a new German constitution. Based on the defense of national and racial homogeneity (*Artgleichheit*), and guided by the principles of leadership and loyalty, Germany should be rebuilt as a threefold totality comprising (1) a bureaucratic apparatus that included the judiciary, (2) a one-party political movement, and (3) a politically neutralized sphere of professional and communal administration (*Selbstverwaltung*).

In matters of international law, Schmitt criticized all global constructions of international legal order and defended a European Monroe Doctrine based on German hegemony. He distrusted concepts of international legal order because they could be used to justify imperialism and illegitimate imperialist intervention in the affairs of foreign states. He also deplored political universalism, because it produced a concept of warfare according to which both the enemy's state and its citizens could be prosecuted as criminals (the difference between the enemy and a criminal being blurred). [See INTERNATIONAL CRIMES.] As Germany approached defeat in World War II, Schmitt tried to discover what historical conditions had once enabled the European states to distinguish between an enemy and a criminal and to conduct war as an honorable duel between honorable adversaries. He believed he had found those conditions in a so-called *Nomos der Erde*, which originally had been shaped by the *jus publicum europaeum*. Schmitt believed that this *Nomos* could be found in a special geopolitical order, based on the division of the world into different areas of influence, dominated by the great European powers. These powers would recognize each other as independent sovereignties united by a common civilization of martial law.

Schmitt compared his own role under the Nazi regime to that of Benito Cereno in Herman Melville's story, who, after a mutiny on his slave ship had succeeded, served under the victors as a pirate, unable to disentangle himself from a situation in which protection was contingent on obedience. Schmitt's teaching, however, was often very near to the "mutinous" ideology which destroyed the Weimar Republic and helped the Nazi movement gain power. Yet by making the character of enmity, among citizens as well as nations, the crucial theme of systematic jurisprudence and political thinking, Schmitt created a new awareness of important problems.

### SCHMOLLER, GUSTAV

Gustav Schmoller (1838-1917), German economist, came from a family of Württemberg civil servants, and he began his own career in the financial department of the Württemberg civil service. This experience gave him practical insights into the administration of a territory with a strong cameralist tradition and may have shaped his belief in the close interrelations between the economy and the government. At the University of Tübingen Schmoller studied *Staatswissenschaften*, a peculiarly German discipline derived from cameralism, which combines public finance, statistics, economics, administrative science, history, and even sociology. Later he became professor of *Staatswissenschaften* at the universities of Halle, 1864-1872; Strassburg, 1872-1882; and finally Berlin, 1882-1913.

In the early 1860s Schmoller defended the commercial treaty between France and the German Zollverein. Since he was supporting the point of view of the Prussian government against that of Württemberg, he ruined his career in Württemberg but gained favor with the Prussian authorities. In the Wilhelmian period, Schmoller became one of the most ardent Prussian patriots. He was appointed the official historian of Brandenburg and Prussia in 1887, became a member of the Prussian Staatsrat (state council) in 1884, and the representative of the University of Berlin in the Herrenhaus (upper house) in 1889. He was also a member of several academies (Berlin, Munich, St. Petersburg, Copenhagen, Vienna, and Rome) and

the recipient of honorary degrees from Breslau and Heidelberg.

As founder and leader of the Verein für Sozialpolitik, the association of German academic economists, and as editor or coeditor of several series of publications (*Staats- und sozialwissenschaftliche Forschungen*, from 1879; *Jahrbuch für Gesetzgebung, Verwaltung und Volkswirtschaft im Deutschen Reiche*—later known simply as *Schmollers Jahrbuch*—from 1881; *Forschungen zur brandenburgischen und preussischen Geschichte*, from 1888; and *Acta borussica*, from 1892) he became one of the first great organizers of research in the social sciences. Thus, he dominated the development of economics and of related social sciences in his country; for several decades, hardly a chair of economics was filled without his approval. He and his followers were called the "younger historical school" because their methodological approach was derived from, but also differed from, the approach of the "older historical school" of Roscher, Hildebrand, and Kries [see ECONOMIC THOUGHT]; they were also called the *Kathedersozialisten* (most nearly translated as academic socialists) because of their sociopolitical aims and were able to influence contemporary social legislation, since Schmoller was close to many high civil servants and to the crown.

In his political activities, Schmoller may be called a conservative social reformer. He was a royalist, favored strong government, and displayed the highest respect for the Prussian civil service; but he was also deeply preoccupied with the "social question," the improvement of the condition of the lower classes. He believed that a variety of means should be used to solve this problem: better education of the working classes; governmental regulation of working conditions; cooperatives; and changes in the law, in institutions, and in the attitudes of the ruling classes. He was hostile both to Manchesterism and to Marxism, but he was open to all kinds of reforms that would produce more "social justice," a concept central to his thinking.

Contributions to the social sciences. Schmoller's interests embraced history, applied statistics, economic and social institutions and behavior (including social psychology), social anthropology, geography, demography, the theory and practice of economic and social policy, and even ethics and philosophy, but he regarded himself primarily as an economist. His voluminous *Grundriss* (1900-1904), comparable in scope, though not in method, to Alfred Marshall's *Principles*, assembled pieces of all these social sciences into a great mosaic or panorama of the social world, past and present.

The only thing the work lacked was an analytical framework to hold the pieces together. Although Schmoller often claimed to have such a framework, he was basically eclectic.

Schmoller's rejection of analytical theory of the Smith-Ricardo type was of the utmost importance for his own thinking and for the development of economics in Germany under his "regime." He believed classical analysis to be useless or at best of minor importance, since it is applicable only to very small and artificially isolated fragments of the social reality that he wanted to perceive in all its many facets. It is not true, as many have asserted and as the term "historical school" suggests, that he wanted to replace analytical theory with purely historical research, but he was convinced that a genuine theory can only be the final outcome of an immense amount of descriptive work on past as well as present events, institutions, and structures. His conception of theory is the central defect in his thought and accounts for most of the weaknesses in his own works and in those inspired by him. It is difficult to decide whether he was led to this position by his inability to grasp the nature of theory or by his ethical disapproval of liberal economic doctrines, which he scorned as "business economics."

**Reception of Schmoller.** Schmoller's view of theory was attacked in 1883 by the Viennese professor Carl Menger, who wrote a treatise on method in the social sciences, *Problems of Economics and Sociology* (*Untersuchungen über die Methode der Socialwissenschaften und der politischen Oekonomie insbesondere*). Schmoller replied in his *Jahrbuch* (1883), and Menger renewed the attack in the pamphlet *Die Irrthümer des Historismus in der deutschen Nationalökonomie* (1884), "which fairly steamed with wrath and of course elicited rebuttal" (Schumpeter 1954, p. 814). This famous *Methodenstreit* dominated the economic and social sciences in Germany for at least two generations.

There can be little doubt that logically Menger was in a far better position. What he advocated as the appropriate methodology for economics was the use of the partial-equilibrium models that have since become the common method of theorists in most parts of the world. Nevertheless, Schmoller was not entirely wrong when he favored a much broader and more differentiated approach. He wanted to grasp all at once what has since become the object of many different branches of the social sciences. As a consequence, he touched on many important things, but often only superficially and seldom with clear insight about the implications of his observations and judgments. He was attacked

not only by theoretical economists but also by professional historians, such as Georg von Below (1904). Interestingly enough, both the theorists and the historians had basically the same objections to the Schmollerian type of social science: both missed a coherent and systematic approach. The issue, then, was not simply one of theory against history, but of how research in the social sciences ought best to be done. Although Schmoller often stated that his method alone was an "exact" one, even his friends and students agreed that he wrote without precision.

The very qualities of Schmoller's work that were criticized in the academic community won him a broad public audience. He took up many urgent issues of the day, examined them from different points of view, and came to general conclusions that many people could agree with. This made him an effective leader of public discussion and a popular, though not a brilliant, academic lecturer. He was at his best when dealing with those issues of social policy (*Sozialpolitik*) that urgently required compromise. In political debates he exhibited a considerable amount of personal commitment and civic courage, fighting against aggressive social conservatism (e.g. Treitschke 1875) as well as against the revolutionary position of Lassalle and Marx and their followers. In these debates he made plain his belief in the necessity of more social justice. However, he did not distinguish clearly between the value judgments he made in political debates and the axioms of his scientific thought. This led to another methodological attack on Schmoller, led by Max Weber and Werner Sombart, to eliminate value judgments from the social sciences (see Weber 1910; Sombart 1910).

**An appraisal of Schmoller.** Given his many weaknesses, one asks what made Schmoller the leader of German social scientists during the Wilhelminian period. Undoubtedly, others were stronger as theorists, as historians, or as sociologists. However, except for Max Weber, who was much younger, no one was quite as universal as Schmoller. Moreover, no one combined so many of the personal qualities of a leader: he was charming but dictatorial; confident in his views but able and willing to accept ideas; basically simple in his thinking but with a broad outlook; fully committed to sharply defined positions but prepared to compromise. Much of his influence appears to derive from his ability to express the leading ideas of his time. He swam with the stream of contemporary opinion, not against it, as is obvious in his views on foreign affairs, on which he had no ideas of his own but shared the nationalistic, imperialistic,

even chauvinistic outlook of the German elite. When the tide of sentiment and opinion turned, shortly after his death in 1917, his views were quickly outdated, and people began to wonder how he could ever have been the great leader he certainly was.

His influence on the development of the social sciences in Germany was, on the whole, rather unfortunate. He is mainly responsible for the neglect of economic theory in Germany between 1870 and 1920, and he can be made indirectly responsible for the extreme reaction that produced the subsequent neglect of economic history in twentieth-century Germany. In his attempt to construct a theory mainly by historical methods, he damaged both theory and history, and hampered their development in Germany for nearly a century. Outside Germany, his influence was never considerable, although American institutional economics was based partly on his ideas.

## SCHRIEKE, BERTRAM

When the Dutch anthropologist Bertram Johannes Otto Schrieke (1890–1945) was studying at the University of Leiden, where he finished his studies with a doctor's degree in "languages and literature of the East Indian archipelago," sociology as a discipline was in its infancy in the Netherlands. It was taught only at the University of Amsterdam, where Schrieke attended the lectures of S. R. Steinmetz—through whom he was influ-

enced by the theories of Max Weber. At Leiden he was a pupil of Snouck Hurgronje, the eminent Islamologist and Arabist; of C. Van Vollenhoven, for adat law; and of other orientalist. His career was to be as diversified as his training.

Schrieke was not a theorist. Rather he took exception to existing theories as being too one-sided or too narrow. He held the view that "a culture forms an organic whole, which cannot be split up into different parts as if these components had no relation to each other," an approach not generally shared in the 1920s (*Indonesian Sociological Studies*, vol. 1, p. 232).

As demonstrated by his lifelong work in the social and economic aspects of the history of Indonesia and of Indonesian foreign contacts, Schrieke's forte lay in maintaining a critical attitude toward the generally accepted approaches to these subjects, which relied on archeology and colonial history.

In his doctoral thesis, *Het boek van Bonang* (1916), he analyzed the text of a manuscript, written in Javanese and ascribed to a legendary Muslim saint, which had been in the library of the University of Leiden since the beginning of the seventeenth century. His study of this manuscript, as well as of the early history of the Portuguese and Dutch trade contacts with Indonesia and of the published material on the voyages of Chinese and Arabs in the previous centuries, enabled him to revise the existing theory that the Islamization of the archipelago was the result of *pénétration pacifique*. He came to the conclusion that Islamization, hitherto considered to be primarily the product of trade relations, had been equally influenced by political conflicts and military struggles. In this work he acknowledged his debt to his mentor, G. P. Rouffaer, honorary member of the Royal Institute for Philology, Geography, and Ethnology of the Netherlands Indies at The Hague, whose own work of collecting and comparing source material was an inspiration to Schrieke.

Returning later to this problem in parts of a wide-ranging study, "Ruler and Realm in Early Java" (published posthumously, in an English translation only; 1957), Schrieke suggested that it is "impossible to understand the spread of Islam in the archipelago unless one takes into account the antagonism between the Muslim traders and the Portuguese," antagonism which caused the Indonesians to side with the Muslims.

During the 1920s, when Schrieke was acting as adviser on native and Arab affairs to the Netherlands Indies government, it was his intention to write a sociological study of the peoples of Sumatra

based on these ideas. He had written only the first, historical section of the "Prolegomena" to this study (see 1925) when he was called upon to conduct an inquiry into the so-called communist uprisings on the west coast of Sumatra in 1926. In order to explain the success of the communists' tactics, Schrieke incorporated in his report facts relating to the historical background and structure of Minangkabau society and dealt with the impact of the introduction of a money economy. He was thus able to point to the factors in this transitional period which had helped to foster the antigovernment attitude of the population. Here again his natural approach was to gather any relevant data, including the seemingly unimportant and the controversial. In 1955 the parts of his report that deal with the situation underlying the uprisings were published in an English translation, together with the above-mentioned "Prolegomena" and a number of his other publications (*Indonesian Sociological Studies*, vol. 1).

The Fourth Pacific Science Congress, convened at Batavia (now Jakarta) in 1929, afforded Schrieke the opportunity of editing a symposium entitled *The Effect of Western Influence on Native Civilisations in the Malay Archipelago*, to which his own contribution was "Native Society in the Transformation Period."

As director of the Netherlands Indies Department of Education from 1929 to 1933, Schrieke stressed the need for a sociological approach to educational problems. He defended the existing diversified educational system, adapted as it was to serve the needs of a heterogeneous population.

He did further field research in applied sociology at the invitation of the Julius Rosenwald Fund, which resulted in *Alien Americans* (1936). This was an "American Dilemma" *avant la lettre*: a one-man attempt to study the Negro problem in the United States and to interpret it against the background of other race relations there.

Apart from the influence he exerted in sociology and history when he was professor of sociology in the law school at Batavia, from 1924 to 1929, and later at the University of Amsterdam, from 1936 to 1945, Schrieke's ideas can best be traced in the work of J. C. van Leur (1934) and M. A. P. Meilink-Roelofs (1962). He fostered surveys of research on both Indonesia and the Netherlands Caribbean territories; he also encouraged such surveys in connection with the work of the International Refugee Colonization Society, established in 1938.

He also applied his organizational ability as museum director of the 150-year-old Batavian Society of Arts and Letters in 1923 and later, from

1938 to 1945, as director of the ethnological department of the Royal Colonial Institute (now Royal Tropical Institute), Amsterdam.

Schrieke died suddenly in London in September 1945 while attending a United Nations conference as a Netherlands government delegate on Indonesian affairs.

## SCHULTZ, HENRY

Henry Schultz (1893-1938), American econometrician, was born in Russian Poland. After attending public schools in New York City and the College of the City of New York, he began his graduate studies at Columbia University in 1916. At Columbia he responded enthusiastically to the influence of Henry L. Moore, but his studies were interrupted by military service in World War I. After the war an army scholarship enabled him to spend the spring and summer terms of 1919 at the London School of Economics and Political Science and at the Galton Laboratory of University College. In London he attended lectures on statistics by A. L. Bowley and Karl Pearson and on economic theory by Edwin Cannan. Once back in the United States, he conducted statistical and economic investigations for, successively, the War Trade Board, the Bureau of the Census, the Bureau of Efficiency, the Institute of Economics, and the Children's Bureau of the United States Department of Labor. His Ph.D. thesis, "The Statistical Law of Demand as Illustrated by the Demand for Sugar," was published in 1925, and in 1926 he joined the department of economics at the University of Chicago, where he remained until his death.

It was Moore's early investigations into the statistical approximation of Marshallian demand curves (1914; 1917) that had a determining influence on Schultz's career. Under Moore's inspiration, Schultz made intensive studies of the works of those economists—Cournot, Walras, and Pareto—who had made the most explicit and sophisticated use of mathematics in formulating economic theory. Schultz also studied probability theory and statistics in considerable depth. His years in various statistical and economic research agencies in Washington, 1920 to 1926, no doubt contributed to his sophistication in the use and interpretation of published economic data.

When Moore ceased writing in 1929, Schultz was almost the only American economist who com-

bined a mastery of the theoretical work of Walras and Pareto with an intense interest in empirical studies of demand. He was fully abreast of the revolution in value theory associated with the names of J. R. Hicks and R. G. D. Allen (1934); they also drew their inspiration from Walras and Pareto. Keynesian macroeconomic theory, however, was not of direct significance to Schultz's work, and the lengthy bibliography of his most important book, *The Theory and Measurement of Demand* (1938, pp. 779-803), contains no reference to Keynes.

Schultz published a number of short notes on regression theory and methods and one major article (1930) on the derivation of standard errors of forecast for curves of various types. In *Statistical Laws of Demand and Supply* (1928), he thoroughly explored the literature on weighted regression—the estimation of a single line or plane of best fit when all variables are subject to error—and was probably the first to apply such methods to economic data. This book presented supply-and-demand curves for sugar, an internationally traded commodity, and led him to write three articles on methods of measuring the effectiveness of a tariff. His contributions to statistical theory must be regarded as by-products of his intense concern with statistical demand analysis, and the work on the tariff was similarly incidental to his main concern. Schultz also published a number of expository articles on the more general contributions of mathematics and statistics to economic research and in book reviews called attention to significant translations or interpretations of Walras and Pareto and to major works on mathematical economics and statistics.

Schultz's lifework is essentially summed up in his monumental 817-page work *The Theory and Measurement of Demand* (1938). Chapters 1, 18, and 19 together provide an excellent statement of the theory of consumer demand, incorporating the Hicks-Allen and Slutsky extensions of Pareto's basic formulation; Chapters 2 and 3 deal with the logical and theoretical validity of various proposed methods for deriving demand curves from time series and from family-budget data; Chapter 4 contains a statement of the assumptions, methods, and procedures to be used in the empirical section. The empirical section, Chapters 5-17, presents statistical demand analyses for ten major crops along with summary comparisons and interpretations of the results for the various commodities, time periods, and functional forms. Further empirical studies are included in Chapters 18 and 19, on related demands. A fifty-page appendix on ele-

sions of Book v of Marshall's *Principles* and other theoretical topics. At Harvard he taught one of the first modern courses in pure theory.

His lectures were never dull; often they were brilliant. But what distinguished Schumpeter's lectures and seminars most was neither their brilliance nor their organization (which occasionally left something to be desired); rather, it was his persistent effort on all occasions, formal or informal, to make it possible for students to work out their own ideas. In nine years of attending his lectures and seminars in Bonn and at Harvard, I remember only two occasions when he talked about his own work and then only at the prodding of his students.

He spent much time with his students outside the classroom. In Bonn he frequently went on walks with them, discoursing, interrupting his walk suddenly to jot down an idea. At Harvard he regularly met his students socially. He also circulated a sheet of paper during each lecture on which six students signed up to see him. He was not the kind of teacher who provided his students with clear-cut answers, to the despair of the less-gifted students. But for others this method had a delayed effect that years later would make them sit up and exclaim, "So this is what Schumpeter meant!"

### The Schumpeterian system

Because of Schumpeter's many-sided gifts and the variety of fields to which he contributed, it is difficult to trace his intellectual ancestry. His teachers at the University of Vienna included Friedrich von Wieser, E. von Phillipovich, and E. von Böhm-Bawerk. But among all economists, he had the greatest esteem for Léon Walras, and he thought very highly of English and American economists, particularly F. Y. Edgeworth and John Bates Clark. The similarity of Schumpeter's thought to Marx's has frequently been noted, although Marx's influence on Schumpeter may have been overestimated because of Schumpeter's ability to admire and understand Marx even when he disagreed with him.

Schumpeter was more aware than many other theoretical economists, the most notable exception being Marx, that economic reality is only a part of total reality. The division of the economic from the noneconomic was for him purely a matter of scientific convenience. He contributed significantly to the understanding of noneconomic, particularly sociological, phenomena, as in his synthesis, *Capitalism, Socialism, and Democracy* (1942). If his work lacks the mathematical precision he urged

upon others, this was not the result of unclear thinking but of the complexity (one might almost say the messiness) of the problems he tackled.

Any brief characterization of an elaborate and subtle system is necessarily something of a caricature. Bearing this limitation in mind, Schumpeter's vision of the economic process might be summarized as follows:

There is only one single historical reality, which consists of unique "events." To understand this reality one must always be aware of its quality of uniqueness. But one must also realize that events are related to each other, not just simultaneously but over time. Simultaneous relationships are the subject of equilibrium theory; intertemporal relationships are the subject of dynamic theory. Both equilibrium theory and dynamic theory are necessary to explain any event at any given moment of time.

**Statics and dynamics.** The essential difference between statics and dynamics—a dichotomy that Schumpeter distinguished from the dichotomy between stationary and evolutionary—is not fully expressed by stating that dynamics involves time and statics does not. For Schumpeter static, or equilibrium, theory deals with processes of adaptation that are found in reality: he believed he could identify particular periods in history in which the economic system was "in the neighborhood of equilibrium." His equilibrium, however, has no normative content; it is not in any sense an ideal state of affairs, a golden age.

It follows, therefore, that the dynamics that concerned Schumpeter was *not* the time sequence of adjustment to some change that had somehow occurred. Rather, he sought to discover what causes the movement away from equilibrium, what is responsible for the destruction of equilibrium. For reasons of scientific convenience, he centered his attention on those disruptions of equilibrium that arise inside the economic system, although he believed that equilibrium can also be disrupted by forces outside the economy, such as wars or natural catastrophes. (While for Marx, and certainly for Lenin, wars arise from the inner contradictions of capitalism, Schumpeter stressed the essentially pacific and constructive nature of capitalism and its evolution.)

**Business cycles.** The distinction between statics and dynamics is fundamental to Schumpeter's ideas on the business cycle. It explains not only why a recession, being an adaptive phenomenon, must follow a boom, but also why a boom requires a different explanation from a recession. It shows

both why historical data are needed to arrive at an explanation and how such data are fitted into a general framework and thereby become meaningful. It explains in what sense business cycles are essential to progress: business cycles occur because equilibrium is destroyed by innovations, and the economy must adapt to the destruction before there can be any further innovation. Finally, the distinction accounts for the institutional requirements that must be met if an economy is to remain dynamic. The essential institutional arrangements are two: first, scope for the operation of innovators, the Schumpeterian entrepreneurs; and second, the possibility for innovators to break into the circular flow of the economy, this being achieved through the creation of credit. Credit creation permits the entrepreneur to take resources out of the income stream for productive purposes *before* he has contributed anything to the income stream.

Schumpeter distinguished three types of business cycles, each of whose length depends on the disturbance that brought it about. He named the cycles for pioneers in business cycle theory. The shortest, the Kitchin cycle, is identified with inventory accumulation and decumulation lasting about three years. The medium cycle, of about 8–11 years, usually referred to as *the* business cycle, he named for Clément Juglar, and he related it to individual innovations, such as new textile machines, dynamos, electric motors, radios, and refrigerators. The long cycle, named for Kondratieff, is caused by the appearance of major innovations, such as railroads or electrification, which cannot be carried through in one “juglar.” Thus, long-run trends become part of cyclical phenomena and, indeed, can be understood as the result of shorter-run changes.

Schumpeter believed that each cycle consists of four phases. He characterized the recovery and recession phases as adaptive processes, while the upswing and depression phases represent movements away from the neighborhood of equilibrium, caused, respectively, by innovation and by such extrinsic and inessential phenomena as speculation, panics, or poor economic policies. The upswing and recession phases are essential to the capitalist process, but the depression and recovery phases are not. Since the acute social and personal hardships occur in the inessential phases, policy can eliminate them.

**Development of Schumpeter's system.** Beginning in 1908, Schumpeter published a series of books in which he progressively developed these economic theories. His first major book was *Das*

*Wesen und der Hauptinhalt der theoretischen Nationalökonomie* (1908), which was probably conceived during his days as a graduate student and written in Cairo. It was a brilliant statement of general equilibrium theory, making clear both what static theory could explain and what it could not. This was followed in 1912 by *The Theory of Economic Development*, which contained the first important vision of the “Schumpeterian system”—a term he would have abhorred. The book dealt primarily with dynamics—the entrepreneurial function, the role of the banking system, and the creation of credit. Finally, in *Business Cycles* (1939), he fleshed out the bones of theory with historical material. Moreover, *Business Cycles* contains numerous partial mathematical models.

**Assessment of the system.** Schumpeter's detailed discussion of historical data in the context of his theory has, of course, led to criticism of his interpretation of particular facts. Also, it has been suggested that his emphasis on the innovating entrepreneur tends to limit his theory to the past. Schumpeter himself felt that reality fitted his three-cycle schema better than his theory warranted, since nothing in his theory required or even suggested any particular regularity of timing. He also felt that he had accomplished his task if he had adequately explained capitalism from the eighteenth century to the early twentieth century, and he apparently agreed that in the future trust-dominated capitalism and planned socialism might make his theory obsolete.

Many years later Schumpeter wrote that he was “trying to construct a theoretic model of the process of economic change in time, or perhaps more clearly, to answer the question how the economic system generates the force which incessantly transforms it” (*Essays*, pp. 158–159). Because of this, and despite his own skepticism about the future relevance of his theory, Schumpeter's approach retains its usefulness in underdeveloped as well as in developed countries, and in socialist as well as in market economies. In order for there to be economic development, the Schumpeterian problem of when to introduce a change, when to introduce an investment, must be solved. There is nothing automatic about the introduction of new investments, and planners, in both market and socialist economies, must think like Schumpeterian entrepreneurs if their plans are to lead to self-sustaining growth. If a theory is understood to be a collection of formulas that can be applied with a minimum of analysis and thought, then Schumpeter's theory is indeed obsolete. But if it is understood to be a

view of the economy that enables a policy maker to ask pertinent questions and develop appropriate programs of action, then the relevance of Schumpeter's thought to any changing economy cannot be doubted.

### Other economic writings

Schumpeter's contribution to the history of economics, like his contribution to economic theory, developed over many years. The posthumously published *History of Economic Analysis* (1954) is an elaboration of his much earlier *Economic Doctrine and Method* (1914). Both are histories of economic theories, which Schumpeter believed develop in the same manner as do theories in the natural sciences. In other words, economic theories, unlike philosophies, are not self-contained and develop over time in a cumulative fashion. The *History of Economic Analysis* was published from an unfinished manuscript. It is, by any standard, an outstanding intellectual achievement. While it met with detailed criticism (for example, Schumpeter was charged with having been less than fair to the neoclassical economists), it is, of course, impossible to say to what extent these criticisms would have been avoided if Schumpeter had lived to finish the work.

Schumpeter also wrote many articles on monetary theory, relating monetary theory to his general view of development. As early as 1917, when it was not common to do so, he discussed money in relation to national income and economic policy. While he was writing a book on monetary theory, Keynes's *Treatise on Money* appeared. Schumpeter admired the *Treatise* and insisted that all his students read it, but he felt that its substance required a complete rewriting of his own work.

### Sociological writings

Schumpeter considered from a sociological point of view a variety of phenomena that others had interpreted in mainly economic terms—imperialism, social classes, taxation, socialism, and even the entrepreneur. He attempted to relate economic phenomena to the larger social context. Thus, for example, he rejected the view that economic explanations can adequately account for the phenomenon of imperialism, which is an "atavism" of social structure and of emotional habits of an individual-psychological nature, and he stressed that any explanation of the entrepreneur must include the social and political conditions necessary for him to fulfill his functions.

Schumpeter brought together his sociological and economic analyses primarily in *Capitalism,*

*Socialism, and Democracy* (1942), a work remarkable for its style as well as for its vision. Essential to his argument is his analysis of Marxian doctrine. Schumpeter did not think that capitalism shows the inherent contradictions that Marx claimed would lead to the immiserization of the masses and to revolution; nor does capitalism per se lead to imperialistic adventures or to wars. But he sympathized with the Marxian idea that the achievements of capitalism, which Marx himself had praised so highly, have their own inherent logic: because capitalism has a historic function to perform, it will come to an end as the function disappears. Socialism is possible, perhaps even inevitable, but what Schumpeter meant by socialism is different from what is commonly understood by the term.

Socialism is defined by Schumpeter as "an institutional pattern in which the control over means of production and over production itself is vested with a central authority—or, as we may say, in which, as a matter of principle, the economic affairs of society belong to the public and not to the private sphere" (1942, p. 167). This is quite consistent with the fact that "some freedom of action must be left, and almost any amount of freedom might be left, to the 'men on the spot,' say, the managers of the individual industries or plants" (p. 168). It is noteworthy that the definition does not necessarily include ownership of the means of production.

Schumpeter made short shrift of the numerous reasons that have been adduced to prove the approaching collapse of capitalism. He argued that capitalism cannot be even approximately identified with perfect competition and, therefore, to criticize it for monopolistic practices or for temporary recessions misses the point. "Capitalism . . . is by nature a form or method of economic change and not only never is but never can be stationary" (1942, p. 82), and most criticism overlooks this essential fact.

The Achilles' heel of capitalism lies elsewhere, namely in its achievements. The very success of capitalism will bring about its doom for two reasons: as societies grow richer, and production and productivity increase spectacularly, the need for further growth and for the specific contribution of the entrepreneur will disappear. Administrators can deal with what will become essentially routine problems, and the desiderata of economic life will shift. At the same time, the successes of capitalism will lead to an increasingly hostile intellectual environment, to a *trahison des clercs*, in which entrepreneurs will find it increasingly difficult to fulfill

their essential function. Schumpeter was also prepared to consider that the process of innovation might itself become more and more routine. He foresaw the eventual triumph of socialism, but he thought its chances for success and indeed its relevance negligible in precisely those situations where most people believed (and still believe) it necessary—to make poor economies grow.

Economically, capitalism has performed miracles, and in another fifty to one hundred years it will have created such a powerful productive machine as to eliminate poverty. (Indeed, Schumpeter's own projections—in Chapter 5—have already been far surpassed.) Culturally, capitalism has brought about the spread of a rational and pacific view of the world: "Modern mathematico-experimental science developed . . . not only along with the social process usually referred to as the Rise of Capitalism, but also outside . . . of scholastic thought and in the face of its contemptuous hostility" (1942, p. 124). The same is true of painting and literature.

Schumpeter also discussed the problem of the transition to socialism. The socialism that can work is one that comes "in the fullness of time," when the problem of poverty has been solved by the preceding creation of a powerful productive economy. Schumpeter believed that he and Marx were basically in agreement on this point:

Evolution was for him [Marx] the parent of socialism. He was much too strongly imbued with a sense of the inherent logic of things social to believe that revolution can replace any part of the work of evolution. . . . The Marxian revolution therefore differs entirely, in nature and in function, from the revolutions both of the bourgeois radical and of the socialist conspirator. It is essentially revolution in the fullness of time. . . . To say that Marx, stripped of phrases, admits of interpretation in a conservative sense is only saying that he can be taken seriously. (1942, p. 58)

If socialism is built on a powerful productive economy, then the problems of transition will be negligible; if this condition does not obtain, these problems of transition may jeopardize the success of socialism. Schumpeter also considered the rationality of socialist decision making, first discussed by Enrico Barone in 1905, and the human problems involved.

According to Schumpeter, socialism can be run on democratic lines. His definition of democracy may not, however, command general assent—an "institutional arrangement for arriving at political decisions in which individuals acquire the power to decide by means of a competitive struggle for the people's vote" (p. 269). What will actually

happen will depend on many accidents as well as on the inherent logic of social (including economic) evolution: "... there is little reason to believe that . . . socialism will mean the advent of the civilization of which orthodox socialists dream. It is much more likely to present fascist features. That would be a strange answer to Marx's prayer. But history sometimes indulges in jokes of questionable taste" (p. 375).

It is difficult to present Schumpeter's thought in a brief form: its complexity is such that the many pages Schumpeter himself devoted to it are entirely necessary. This complexity might have prevented the development of a Schumpeter school, even if he himself had not actively discouraged its formation. Moreover, it is not easy to locate Schumpeter in a history of economic analysis: although he was an Austrian by birth and training, he was not an "Austrian" economist. He belongs to that recent trend in economics that is characterized by an absence of schools of economic thought, though not of good economists. The economists Schumpeter himself trained will never put reality into the strait-jacket of any particular theory; they will be able to use any logical theory while remaining conscious of the variety and uniqueness of the real social and economic problems.

## SCHUTZ, ALFRED

Alfred Schutz (1899-1959) was born in Austria, studied at the University of Vienna, and from 1939 until his death lived in New York City, where he was professor of philosophy and sociology at the New School for Social Research. His principal philosophical work consisted of the application of Edmund Husserl's phenomenology to the problems of social reality, while his major methodological contribution was an attempt to relate phenomenological concepts to the sociology of Max Weber. He believed that the cardinal problem for the social sciences is the study of the world of daily life, of the common-sense reality that each individual shares with his fellow men in a taken-for-granted

manner, and both his major intellectual efforts focused on this problem. As Schutz saw it, the task of the phenomenological philosopher concerned with social reality is to uncover, describe, and analyze the essential features of this mundane world; and consequently all of his writings, beginning with *The Phenomenology of the Social World* (1932), take the reality of everyday life as a point of departure and as a subject for detailed examination.

For Schutz, the world of common-sense reality rests on certain basic epistemological presuppositions: that the mundane world exists, that man and his fellows exist in that world, and that man can communicate with Others. In daily life, men take for granted the reality of their experience: they assume, naively, that they share the same world with all other "normal" perceivers; and they assume that were they to change places with Others, they would see the world in essentially the same way the Others do.

Upon analysis, it is found that these fundamental presuppositions imply a number of structural characteristics. (1) The "biographical situation" of the individual depends on his particular location in the social world as he himself defines it and as he interprets that location in terms of his previous experiences. The biographical situation is unique to the individual, although it includes typical features he does share with Others. (2) Common-sense man possesses a "stock of knowledge at hand." It includes elements handed down to him by Others, parents and teachers among them, and it is in a typically organized form. This knowledge is accepted without question as generally valid, though it is always potentially questionable. (3) The spatial coordinates of "here and there" are essential features of the social matrix by which the individual locates himself. The individual's own body is the reference point in terms of which he locates himself as "here" and the Other as "there." (4) The "alter ego" is given to the individual as a being like himself in a mundane world. Moreover, the Other exists simultaneously with the self, his thought is grasped in a vivid present, and alter ego's speech and the individual's listening coexist in a relationship that is the essence of intersubjectivity. (5) Ego's world, as an intersubjective social reality, includes alter egos with different temporal and spatial characteristics: predecessors, or those who lived before him and are known to him through report, contemporaries, who share the same temporal world; consociates, or those who are alive at the same time and who also share ego's spatial segment of the world through face-to-

face relationships; successors, who will live after he dies, including those who will be born only after he is dead. The social world is as much constituted by consciousness of predecessors and successors as it is by contemporaries and consociates. To explain the structural relationships that hold among all of these aspects of social order, a theory of social action is necessary.

Schutz distinguished between "action" and "act." Action is understood as purposive conduct projected by the actor; an act is defined as accomplished action. Action has a subjective form as well as an objective form: purposively *refraining* from doing something is no less action than overtly behaving in one way or another. What is of decisive importance to Schutz's conception of action is his view that action is grounded in the interpretative consciousness of the actor. It is at this point that Schutz turned to Weber, in particular to his conception of interpretative understanding (*Verstehen*) and to his postulate of the subjective interpretation of meaning. To understand social action is to grasp the meaning which the actor gives to or bestows upon his action, to comprehend what that action means to *him*. The "subjective" interpretation of meaning signified for Weber what the actor *means* by his action, not, as Schutz stressed, some private idiosyncratic and unverifiable domain.

In Schutz's adaptation of Weber, subjective interpretation of meaning appears primarily as a fundamental typification of the common-sense world. All men in mundane life, then, practice *Verstehen*, but there is a distinction between *Verstehen* (1) as an experiential form of common-sense knowledge, (2) as an epistemological problem, and (3) as a distinctive method of the social sciences. Schutz believed that it was the great merit of such men as Durkheim, Pareto, Marshall, and Veblen, and above all of Weber, to have developed the technique that "consists in replacing the human beings which the social scientist observes as an actor on the social stage by puppets created by himself, in other words, in constructing ideal types of actors" (*Collected Papers*, vol. 2, p. 17). The social scientist, according to Schutz, proceeds as follows:

[He] observes certain events within the social world as caused by human activity and he begins to establish a type of such events. Afterwards he coordinates with these typical acts typical because motives and in-order-to motives which he assumes as invariable in the mind of an imaginary actor. Thus he constructs a personal ideal type, which means the model of an actor whom he imagines gifted with a consciousness. . . . The social scientist places these constructed types in

a setting which contains all the elements of the situation in the social world relevant for the performance of the typical act under inquiry. Moreover, he associates with him other personal ideal types with motives apt to provoke typical reactions to the first ideal type's typical act. So he arrives at a model of the social world, or better at a reconstruction of it. (*ibid.*, pp. 17-18)

Action is never an isolated phenomenon; it has its phenomenological "horizons" of relevance and relatedness to social reality, and it has its "motivation." As already noted, typical acts have two kinds of motives, "in-order-to" motives and "because" motives. The first are explained in terms of the actor's goals and ends; the second, in terms of his background and disposition. The in-order-to motive is "the future state of affairs to be realized by the projected action," and the project itself is determined by the because motive, which in turn is dominated by the past tense. Other people's acts can be fully understood only insofar as their because and in-order-to motives are known, but since this is impossible, it must suffice to know their typical motives, including their reference to typical situations, typical ends, typical means, etc. (*ibid.*, pp. 11-12).

The temporal disequilibrium between the two orders of motive suggests a larger problem in the conception of the ego. According to Schutz, the ego cannot seize its own immediacy; it can capture itself only as an object of a reflexive act. Schutz here came close to George H. Mead's distinction between the "I" and "me" aspects of the self. He pointed, however, to a larger implication of the distinction, for man is understood as a being who presents himself to Others, takes his place in the social world, and, finally, knows himself only in a partial and fragmentary way. Such fragmentation is itself a primordial typification of reality.

Schutz's philosophical position has significance for the choice of models to be used in the social sciences, and it suggests, in particular, that the use of natural science models is not satisfactory. He believed that the natural and social sciences differ qualitatively: the natural sciences investigate objects that are constructs of the first degree, i.e., objects in the field of the scientific observer; the social sciences are properly concerned with second-degree constructs, i.e., objects that not only are themselves in a world but that also *have* a world. The human beings who are the central concern of the social scientist are interpreters of their own lives and actions. The task of the social scientist is to comprehend the world of daily life (*Lebenswelt*) from which these lives derive their significance, and the phenomenological approach

—its concern with essential structure, with founding relationships, with “sedimentation” of meaning, and with the uncovering of root presuppositions—provides the means by which social science may reconstruct mundane reality. At the same time, the use of *Verstehen* and of the subjective interpretation of meaning may lead to valid knowledge.

Although Schutz's work is profoundly indebted to Husserl and Max Weber, it has affinities with that of other European thinkers, Henri Bergson and Georg Simmel in particular. In the Anglo-American tradition, Schutz found the thought of Santayana, Whitehead, and James especially congenial. The sociologists who influenced him the most were Cooley, Thomas, and Mead. All these men stressed the activity of the actor and his action in relation to the experiential world. It was Schutz's distinctive achievement to develop these intellectual orientations by centering on the paradigm of action instead of the traditional theme of perception and by approaching both actor and action by way of the typifications of common-sense life. In the last decade, Schutz's work has aroused increasing interest among both philosophers and social scientists in the implications of phenomenology for a humanistic sociology and a theory of man.

### I

#### THE HISTORY OF SCIENCE

As an independent professional discipline, the history of science is a new field still emerging from a long and varied prehistory. Only since 1950, and initially only in the United States, has the majority of even its youngest practitioners been trained for, or committed to, a full-time scholarly career in the field. From their predecessors, most of whom were historians only by avocation and thus derived their goals and values principally from some other field, this younger generation inherits a constellation of sometimes irreconcilable objectives. The resulting tensions, though they have relaxed with increasing maturation of the profession, are still perceptible, particularly in the varied primary audiences to which the literature of the history of science continues to be addressed. Under the circumstances any brief report on development and current state is inevitably more personal and prognostic than for a longer-established profession.

**Development of the field.** Until very recently most of those who wrote the history of science were practicing scientists, sometimes eminent ones. Usually history was for them a by-product of pedagogy. They saw in it, besides intrinsic appeal, a means to elucidate the concepts of their specialty, to establish its tradition, and to attract students. The historical section with which so many technical treatises and monographs still open is contemporary illustration of what was for many centuries the primary form and exclusive source for the history of science. That traditional genre appeared in classical antiquity both in historical sections of technical treatises and in a few independent histories of the most developed ancient sciences, astronomy and mathematics. Similar works—together with a growing body of heroic biography—had a continuous history from the Renaissance through the eighteenth century, when their production was much stimulated by the Enlightenment's vision of science as at once the source and the exemplar of progress. From the last fifty years of that period come the earliest historical studies that are sometimes still used as such, among them the historical narratives embedded in

the technical works of Lagrange (mathematics) as well as the imposing separate treatises by Montucla (mathematics and physical science), Priestley (electricity and optics), and Delambre (astronomy). In the nineteenth and early twentieth centuries, though alternative approaches had begun to develop, scientists continued to produce both occasional biographies and magistral histories of their own specialties, for example, Kopp (chemistry), Poggendorff (physics), Sachs (botany), Zittel and Geikie (geology), and Klein (mathematics).

A second main historiographic tradition, occasionally indistinguishable from the first, was more explicitly philosophical in its objectives. Early in the seventeenth century Francis Bacon proclaimed the utility of histories of learning to those who would discover the nature and proper use of human reason. Condorcet and Comte are only the most famous of the philosophically inclined writers who, following Bacon's lead, attempted to base normative descriptions of true rationality on historical surveys of Western scientific thought. Before the nineteenth century this tradition remained predominantly programmatic, producing little significant historical research. But then, particularly in the writings of Whewell, Mach, and Duhem, philosophical concerns became a primary motive for creative activity in the history of science, and they have remained important since.

Both of these historiographic traditions, particularly when controlled by the textual-critical techniques of nineteenth-century German political history, produced occasional monuments of scholarship, which the contemporary historian ignores at his peril. But they simultaneously reinforced a concept of the field that has today been largely rejected by the nascent profession. The objective of these older histories of science was to clarify and deepen an understanding of *contemporary* scientific methods or concepts by displaying their evolution. Committed to such goals, the historian characteristically chose a single established science or branch of science—one whose status as sound knowledge could scarcely be doubted—and described when, where, and how the elements that in his day constituted its subject matter and presumptive method had come into being. Observations, laws, or theories which contemporary science had set aside as error or irrelevancy were seldom considered unless they pointed a methodological moral or explained a prolonged period of apparent sterility. Similar selective principles governed discussion of factors external to science. Religion, seen as a hindrance, and technology, seen as an occasional prerequisite to advance in instrumenta-

tion, were almost the only such factors which received attention. The outcome of this approach has recently been brilliantly parodied by the philosopher Joseph Agassi.

Until the early nineteenth century, of course, characteristics very much like these typified most historical writing. The romantics' passion for distant times and places had to combine with the scholarly standards of Biblical criticism before even general historians could be brought to recognize the interest and integrity of value systems other than their own. (The nineteenth century is, for example, the period when the Middle Ages were first observed to have a history.) That transformation of sensibility which most contemporary historians would suppose essential to their field was not, however, at once reflected in the history of science. Though they agreed about nothing else, both the romantic and the scientist-historian continued to view the development of science as a quasi-mechanical march of the intellect, the successive surrender of nature's secrets to sound methods skillfully deployed. Only in this century have historians of science gradually learned to see their subject matter as something different from a chronology of accumulating positive achievement in a technical specialty defined by hindsight. A number of factors contributed to this change.

Probably the most important was the influence, beginning in the late nineteenth century, of the history of philosophy. In that field only the most partisan could feel confident of his ability to distinguish positive knowledge from error and superstition. Dealing with ideas that had since lost their appeal, the historian could scarcely escape the force of an injunction which Bertrand Russell later phrased succinctly: "In studying a philosopher, the right attitude is neither reverence nor contempt, but first a kind of hypothetical sympathy, until it is possible to know what it feels like to believe in his theories." That attitude toward past thinkers came to the history of science from philosophy. Partly it was learned from men like Lange and Cassirer who dealt historically with people or ideas that were also important for scientific development. (Burt's *Metaphysical Foundations of Modern Physical Science* and Lovejoy's *Great Chain of Being* were, in this respect, especially influential.) And partly it was learned from a small group of Neo-Kantian epistemologists, particularly Brunschvicg and Meyerson, whose search for quasi-absolute categories of thought in older scientific ideas produced brilliant genetic analyses of concepts which the main tradition in the history of science had misunderstood or dismissed.

These lessons were reinforced by another deci-

sive event in the emergence of the contemporary profession. Almost a century after the Middle Ages had become important to the general historian, Pierre Duhem's search for the sources of modern science disclosed a tradition of medieval physical thought which, in contrast to Aristotle's physics, could not be denied an essential role in the transformation of physical theory that occurred in the seventeenth century. Too many of the elements of Galileo's physics and method were to be found there. But it was not possible, either, to assimilate it quite to Galileo's physics and to that of Newton, leaving the structure of the so-called Scientific Revolution unchanged but extending it greatly in time. The essential novelties of seventeenth-century science would be understood only if medieval science were explored first on its own terms and then as the base from which the "New Science" sprang. More than any other, that challenge has shaped the modern historiography of science. The writings which it has evoked since 1920, particularly those of E. J. Dijksterhuis, Anneliese Maier, and especially Alexandre Koyré, are the models which many contemporaries aim to emulate. In addition, the discovery of medieval science and its Renaissance role has disclosed an area in which the history of science can and must be integrated with more traditional types of history. That task has barely begun, but the pioneering synthesis by Butterfield and the special studies by Panofsky and Frances Yates mark a path which will surely be broadened and followed.

A third factor in the formation of the modern historiography of science has been a repeated insistence that the student of scientific development concern himself with positive knowledge as a whole and that general histories of science replace histories of special sciences. Traceable as a program to Bacon, and more particularly to Comte, that demand scarcely influenced scholarly performance before the beginning of this century, when it was forcefully reiterated by the universally venerated Paul Tannery and then put to practice in the monumental researches of George Sarton. Subsequent experience has suggested that the sciences are not, in fact, all of a piece and that even the superhuman erudition required for a general history of science could scarcely tailor their joint evolution to a coherent narrative. But the attempt has been crucial, for it has highlighted the impossibility of attributing to the past the divisions of knowledge embodied in contemporary science curricula. Today, as historians increasingly turn back to the detailed investigation of individual branches of science, they study fields which actually existed

in the periods that concern them, and they do so with an awareness of the state of other sciences at the time.

Still more recently, one other set of influences has begun to shape contemporary work in the history of science. Its result is an increased concern, deriving partly from general history and partly from German sociology and Marxist historiography, with the role of nonintellectual, particularly institutional and socioeconomic, factors in scientific development. Unlike the ones discussed above, however, these influences and the works responsive to them have to date scarcely been assimilated by the emerging profession. For all its novelties, the new historiography is still directed predominantly to the evolution of scientific ideas and of the tools (mathematical, observational, and experimental) through which these interact with each other and with nature. Its best practitioners have, like Koyré, usually minimized the importance of non-intellectual aspects of culture to the historical developments they consider. A few have acted as though the obtrusion of economic or institutional considerations into the history of science would be a denial of the integrity of science itself. As a result, there seem at times to be two distinct sorts of history of science, occasionally appearing between the same covers but rarely making firm or fruitful contact. The still dominant form, often called the "internal approach," is concerned with the substance of science as knowledge. Its newer rival, often called the "external approach," is concerned with the activity of scientists as a social group within a larger culture. Putting the two together is perhaps the greatest challenge now faced by the profession, and there are increasing signs of a response. Nevertheless, any survey of the field's present state must unfortunately still treat the two as virtually separate enterprises.

**Internal history.** What are the maxims of the new internal historiography? Insofar as possible (it is never entirely so, nor could history be written if it were), the historian should set aside the science that he knows. His science should be learned from the textbooks and journals of the period he studies, and he should master these and the indigenous traditions they display before grappling with innovators whose discoveries or inventions changed the direction of scientific advance. Dealing with innovators, the historian should try to think as they did. Recognizing that scientists are often famous for results they did not intend, he should ask what problems his subject worked at and how these became problems for him. Recognizing that a historic discovery is rarely

quite the one attributed to its author in later textbooks (pedagogic goals inevitably transform a narrative), the historian should ask what his subject thought he had discovered and what he took the basis of that discovery to be. And in this process of reconstruction the historian should pay particular attention to his subject's apparent errors, not for their own sake but because they reveal far more of the mind at work than do the passages in which a scientist seems to record a result or an argument that modern science still retains.

For at least thirty years the attitudes which these maxims are designed to display have increasingly guided the best interpretive scholarship in the history of science, and it is with scholarship of that sort that this article is predominantly concerned. (There are other types, of course, though the distinction is not sharp, and much of the most worthwhile effort of historians of science is devoted to them. But this is not the place to consider work like that of, say, Needham, Neugebauer, and Thorndike, whose indispensable contribution has been to establish and make accessible texts and traditions previously known only through myth.) Nevertheless, the subject matter is immense; there have been few professional historians of science (in 1950 scarcely more than half a dozen in the United States); and their choice of topic has been far from random. There remain vast areas for which not even the basic developmental lines are clear.

Probably because of their special prestige, physics, chemistry, and astronomy dominate the historical literature of science. But even in these fields effort has been unevenly distributed, particularly in this century. Because they sought contemporary knowledge in the past, the nineteenth-century scientist-historians compiled surveys which often ranged from antiquity to their own day or close to it. In the twentieth century a few scientists, like Dugas, Jammer, Partington, Truesdell, and Whitaker, have written from a similar viewpoint, and some of their surveys carry the history of special fields close to the present. But few practitioners of the most developed sciences still write histories, and the members of the emerging profession have up to this time been far more systematically and narrowly selective, with a number of unfortunate consequences. The deep and sympathetic immersion in the sources which their work demands virtually prohibits wide-ranging surveys, at least until more of the field has been examined in depth. Starting with a clean slate, as they at least feel they are, this group naturally tries first to establish the early phases of a science's development,

and few get beyond that point. Besides, until the last few years almost no member of the new group has had sufficient command of the science (particularly mathematics, usually the decisive hurdle) to become a vicarious participant in the more recent research of the technically most developed disciplines.

As a result, though the situation is now changing rapidly with the entry both of more and of better-prepared people into the field, the recent literature of the history of science tends to end at the point where the technical source materials cease to be accessible to a man with elementary college scientific training. There are fine studies of mathematics to Leibniz (Boyer, Michel); of astronomy and mechanics to Newton (Clagett, Costabel, Dijksterhuis, Koyré, and Maier), of electricity to Coulomb (Cohen), and of chemistry to Dalton (Boas, Crosland, Daumas, Guerlac, Metzger). But almost no work within the new tradition has as yet been published on the mathematical physical science of the eighteenth century or on any physical science in the nineteenth.

For the biological and earth sciences, the literature is even less well developed, partly because only those subspecialties which, like physiology, relate closely to medicine had achieved professional status before the late nineteenth century. There are few of the older surveys by scientists, and the members of the new profession are only now beginning in any number to explore these fields. In biology at least there is prospect of rapid change, but up to this point the only areas much studied are nineteenth-century Darwinism and the anatomy and physiology of the sixteenth and seventeenth centuries. On the second of these topics, however, the best of the book-length studies (e.g., O'Malley and Singer) deal usually with special problems and persons and thus scarcely display an evolving scientific tradition. The literature on evolution, in the absence of adequate histories of the technical specialties which provided Darwin with both data and problems, is written at a level of philosophical generality which makes it hard to see how his *Origin of Species* could have been a major achievement, much less an achievement in the sciences. Dupree's model study of the botanist Asa Gray is among the few noteworthy exceptions.

As yet the new historiography has not touched the social sciences. In these fields the historical literature, where it exists, has been produced entirely by practitioners of the science concerned, Boring's *History of Experimental Psychology* being perhaps the outstanding example. Like the older histories of the physical sciences, this literature is

often indispensable, but as history it shares their limitations. (The situation is typical for relatively new sciences: practitioners in these fields are ordinarily expected to know about the development of their specialties, which thus regularly acquire a quasi-official history; thereafter something very like Gresham's law applies.) This area therefore offers particular opportunities both to the historian of science and, even more, to the general intellectual or social historian, whose background is often especially appropriate to the demands of these fields. The preliminary publications of Stocking on the history of American anthropology provide a particularly fruitful example of the perspective which the general historian can apply to a scientific field whose concepts and vocabulary have only very recently become esoteric.

**External history.** Attempts to set science in a cultural context which might enhance understanding both of its development and of its effects have taken three characteristic forms, of which the oldest is the study of scientific institutions. Bishop Sprat prepared his pioneering history of the Royal Society of London almost before that organization had received its first charter, and there have since been innumerable in-house histories of individual scientific societies. These books are, however, useful principally as source materials for the historian, and only in this century have students of scientific development started to make use of them. Simultaneously they have begun seriously to examine the other types of institutions, particularly educational, which may promote or inhibit scientific advance. As elsewhere in the history of science, most of the literature on institutions deals with the seventeenth century. The best of it is scattered through periodicals (the once standard book-length accounts are regrettably out-of-date) from which it can be retrieved, together with much else concerning the history of science, through the annual "Critical Bibliography" of the journal *Isis* and through the quarterly *Bulletin signalétique* of the Centre National de la Recherche Scientifique, Paris. Guerlac's classic study on the professionalization of French chemistry, Schofield's history of the Lunar Society, and a recent collaborative volume (Taton) on scientific education in France are among the very few works on eighteenth-century scientific institutions. For the nineteenth, only Cardwell's study of England, Dupree's of the United States, and Vucinich's of Russia begin to replace the fragmentary but immensely suggestive remarks scattered, often in footnotes, through the first volume of Merz's *History of European Thought in the Nineteenth Century*.

Intellectual historians have frequently considered the impact of science on various aspects of Western thought, particularly during the seventeenth and eighteenth centuries. For the period since 1700, however, these studies are peculiarly unsatisfying insofar as they aim to demonstrate the influence, and not merely the prestige, of science. The name of a Bacon, a Newton, or a Darwin is a potent symbol: there are many reasons to invoke it besides recording a substantive debt. And the recognition of isolated conceptual parallels, e.g., between the forces that keep a planet in its orbit and the system of checks and balances in the U.S. constitution, more often demonstrates interpretive ingenuity than the influence of science on other areas of life. No doubt scientific concepts, particularly those of broad scope, do help to change extrascientific ideas. But the analysis of their role in producing this kind of change demands immersion in the literature of science. The older historiography of science does not, by its nature, supply what is needed, and the new historiography is too recent and its products too fragmentary to have had much effect. Though the gap seems small, there is no chasm that more needs bridging than that between the historian of ideas and the historian of science. Fortunately there are a few works to point the way. Among the more recent are Nicolson's pioneering studies of science in seventeenth- and eighteenth-century literature, Westfall's discussion of natural religion, Gillispie's chapter on science in the Enlightenment, and Roger's monumental survey of the role of the life sciences in eighteenth-century French thought.

The concern with institutions and that with ideas merge naturally in a third approach to scientific development. This is the study of science in a geographical area too small to permit concentration on the evolution of any particular technical specialty but sufficiently homogeneous to enhance an understanding of science's social role and setting. Of all the types of external history, this is the newest and most revealing, for it calls forth the widest range of historical and sociological experience and skill. The small but rapidly growing literature on science in America (Dupree, Hindle, Shryock) is a prominent example of this approach, and there is promise that current studies of science in the French Revolution may yield similar illumination. Merz, Lilley, and Ben-David point to aspects of the nineteenth century on which much similar effort must be expended. The topic which has, however, evoked the greatest activity and attention is the development of science in seventeenth-century England. Because it has become the

center of vociferous debate both about the origin of modern science and about the nature of the history of science, this literature is an appropriate focus for separate discussion. Here it stands for a type of research: the problems it presents will provide perspective on the relations between the internal and external approaches to the history of science.

**The Merton thesis.** The most visible issue in the debate about seventeenth-century science has been the so-called Merton thesis, really two overlapping theses with distinguishable sources. Both aim ultimately to account for the special productivity of seventeenth-century science by correlating its novel goals and values—summarized in the program of Bacon and his followers—with other aspects of contemporary society. The first, which owes something to Marxist historiography, emphasizes the extent to which the Baconians hoped to learn from the practical arts and in turn to make science useful. Repeatedly they studied the techniques of contemporary craftsmen—glassmakers, metallurgists, mariners, and the like—and many also devoted at least a portion of their attention to pressing practical problems of the day, e.g., those of navigation, land drainage, and deforestation. The new problems, data, and methods fostered by these novel concerns are, Merton supposes, a principal reason for the substantive transformation experienced by a number of sciences during the seventeenth century. The second thesis points to the same novelties of the period but looks to Puritanism as their primary stimulant. (There need be no conflict. Max Weber, whose pioneering suggestion Merton was investigating, had argued that Puritanism helped to legitimize a concern with technology and the useful arts.) The values of settled Puritan communities—for example, an emphasis upon justification through works and on direct communion with God through nature—are said to have fostered both the concern with science and the empirical, instrumental, and utilitarian tone which characterized it during the seventeenth century.

Both of these theses have since been extended and also attacked with vehemence, but no consensus has emerged. (An important confrontation, centering on papers by Hall and de Santillana, appears in the symposium of the Institute for the History of Science edited by Clagett; Zilsel's pioneering paper on William Gilbert can be found in the collection of relevant articles from the *Journal of the History of Ideas* edited by Wiener and Noland. Most of the rest of the literature, which is voluminous, can be traced through the

footnotes in a recently published controversy over the work of Christopher Hill.) In this literature the most persistent criticisms are those directed to Merton's definition and application of the label "Puritan," and it now seems clear that no term so narrowly doctrinal in its implications will serve. Difficulties of this sort can surely be eliminated, however, for the Baconian ideology was neither restricted to scientists nor uniformly spread through all classes and areas of Europe. Merton's label may be inadequate, but there is no doubt that the phenomenon he describes did exist. The more significant arguments against his position are the residual ones which derive from the recent transformation in the history of science. Merton's image of the Scientific Revolution, though long-standing, was rapidly being discredited as he wrote, particularly in the role it attributed to the Baconian movement.

Participants in the older historiographic tradition did sometimes declare that science as they conceived it owed nothing to economic values or religious doctrine. Nevertheless, Merton's emphases on the importance of manual work, experimentation, and the direct confrontation with nature were familiar and congenial to them. The new generation of historians, in contrast, claims to have shown that the radical sixteenth- and seventeenth-century revisions of astronomy, mathematics, mechanics, and even optics owed very little to new instruments, experiments, or observations. Galileo's primary method, they argue, was the traditional thought experiment of scholastic science brought to a new perfection. Bacon's naive and ambitious program was an impotent delusion from the start. The attempts to be useful failed consistently; the mountains of data provided by new instruments were of little assistance in the transformation of existing scientific theory. If cultural novelties are required to explain why men like Galileo, Descartes, and Newton were suddenly able to see well-known phenomena in a new way, those novelties are predominantly intellectual and include Renaissance Neoplatonism, the revival of ancient atomism, and the rediscovery of Archimedes. Such intellectual currents were, however, at least as prevalent and productive in Roman Catholic Italy and France as in Puritan circles in Britain or Holland. And nowhere in Europe, where these currents were stronger among courtiers than among craftsmen, do they display a significant debt to technology. If Merton were right, the new image of the Scientific Revolution would apparently be wrong.

In their more detailed and careful versions,

which include essential qualification, these arguments are entirely convincing, up to a point. The men who transformed scientific theory during the seventeenth century sometimes talked like Baconians, but it has yet to be shown that the ideology which a number of them embraced had a major effect, substantive or methodological, on their central contributions to science. Those contributions are best understood as the result of the internal evolution of a cluster of fields which, during the sixteenth and seventeenth centuries, were pursued with renewed vigor and in a new intellectual milieu. That point, however, can be relevant only to the revision of the Merton thesis, not to its rejection. One aspect of the ferment which historians have regularly labeled "the Scientific Revolution" was a radical programmatic movement centering in England and the Low Countries, though it was also visible for a time in Italy and France. That movement, which even the present form of Merton's argument does make more comprehensible, drastically altered the appeal, the locus, and the nature of much scientific research during the seventeenth century, and the changes have been permanent. Very likely, as contemporary historians argue, none of these novel features played a large role in transforming scientific concepts during the seventeenth century, but historians must learn to deal with them nonetheless. Perhaps the following suggestions, whose more general import will be considered in the next section, may prove helpful.

Omitting the biological sciences, for which close ties to medical crafts and institutions dictate a more complex developmental pattern, the main branches of science transformed during the sixteenth and seventeenth centuries were astronomy, mathematics, mechanics, and optics. It is their development which makes the Scientific Revolution seem a revolution in concepts. Significantly, however, this cluster of fields consists exclusively of classical sciences. Highly developed in antiquity, they found a place in the medieval university curriculum where several of them were significantly further developed. Their seventeenth-century metamorphosis, in which university-based men continued to play a significant role, can reasonably be portrayed as primarily an extension of an ancient and medieval tradition developing in a new conceptual environment. Only occasionally need one have recourse to the Baconian programmatic movement when explaining the transformation of these fields.

By the seventeenth century, however, these were not the only areas of intense scientific activity, and the others—among them the study of electricity

and magnetism, of chemistry, and of thermal phenomena—display a different pattern. As sciences, as fields to be scrutinized systematically for an increased understanding of nature, they were all novelties during the Scientific Revolution. Their main roots were not in the learned university tradition but often in the established crafts, and they were all critically dependent both on the new program of experimentation and on the new instrumentation which craftsmen often helped to introduce. Except occasionally in medical schools, they rarely found a place in universities before the nineteenth century, and they were meanwhile pursued by amateurs loosely clustered around the new scientific societies that were the institutional manifestation of the Scientific Revolution. Obviously these are the fields, together with the new mode of practice they represent, which a revised Merton thesis may help us understand. Unlike that in the classical sciences, research in these fields added little to man's understanding of nature during the seventeenth century, a fact which has made them easy to ignore when evaluating Merton's viewpoint. But the achievements of the late eighteenth and of the nineteenth centuries will not be comprehensible until they are taken fully into account. The Baconian program, if initially barren of conceptual fruits, nevertheless inaugurated a number of the major modern sciences.

**Internal and external history.** Because they underscore distinctions between the earlier and later stages of a science's evolution, these remarks about the Merton thesis illustrate aspects of scientific development recently discussed in a more general way by Kuhn. Early in the development of a new field, he suggests, social needs and values are a major determinant of the problems on which its practitioners concentrate. Also during this period, the concepts they deploy in solving problems are extensively conditioned by contemporary common sense, by a prevailing philosophical tradition, or by the most prestigious contemporary sciences. The new fields which emerged in the seventeenth century and a number of the modern social sciences provide examples. Kuhn argues, however, that the later evolution of a technical specialty is significantly different in ways at least foreshadowed by the development of the classical sciences during the Scientific Revolution. The practitioners of a mature science are men trained in a sophisticated body of traditional theory and of instrumental, mathematical, and verbal technique. As a result, they constitute a special subculture, one whose members are the exclusive audience for, and judges of, each other's work. The problems on which such

specialists work are no longer presented by the external society but by an internal challenge to increase the scope and precision of the fit between existing theory and nature. And the concepts used to resolve these problems are normally close relatives of those supplied by prior training for the specialty. In short, compared with other professional and creative pursuits, the practitioners of a mature science are effectively insulated from the cultural milieu in which they live their extra-professional lives.

That quite special, though still incomplete, insulation is the presumptive reason why the internal approach to the history of science, conceived as autonomous and self-contained, has seemed so nearly successful. To an extent unparalleled in other fields, the development of an individual technical specialty can be understood without going beyond the literature of that specialty and a few of its near neighbors. Only occasionally need the historian take note of a particular concept, problem, or technique which entered the field from outside. Nevertheless, the apparent autonomy of the internal approach is misleading in essentials, and the passion sometimes expended in its defense has obscured important problems. The insulation of a mature scientific community suggested by Kuhn's analysis is an insulation primarily with respect to concepts and secondarily with respect to problem structure. There are, however, other aspects of scientific advance, such as its timing. These do depend critically on the factors emphasized by the external approach to scientific development. Particularly when the sciences are viewed as an interacting group rather than as a collection of specialties, the cumulative effects of external factors can be decisive.

Both the attraction of science as a career and the differential appeal of different fields are, for example, significantly conditioned by factors external to science. Furthermore, since progress in one field is sometimes dependent on the prior development of another, differential growth rates may affect an entire evolutionary pattern. Similar considerations, as noted above, play a major role in the inauguration and initial form of new sciences. In addition, a new technology or some other change in the conditions of society may selectively alter the felt importance of a specialty's problems or even create new ones for it. By doing so they may sometimes accelerate the discovery of areas in which an established theory ought to work but does not, thereby hastening its rejection and replacement by a new one. Occasionally, they may even shape the substance of that new theory

by ensuring that the crisis to which it responds occurs in one problem area rather than another. Or again, through the crucial intermediary of institutional reform, external conditions may create new channels of communication between previously disparate specialties, thus fostering cross-fertilization which would otherwise have been absent or long delayed.

There are numerous other ways, including direct subsidy, in which the larger culture impinges on scientific development, but the preceding sketch should sufficiently display a direction in which the history of science must now develop. Though the internal and external approaches to the history of science have a sort of natural autonomy, they are, in fact, complementary concerns. Until they are practiced as such, each drawing from the other, important aspects of scientific development are unlikely to be understood. That mode of practice has hardly yet begun, as the response to the Merton thesis indicates, but perhaps the analytic categories it demands are becoming clear.

The relevance of the history of science. Turning in conclusion to the question about which judgments must be the most personal of all, one may ask about the potential harvest to be reaped from the work of this new profession. First and foremost will be more and better histories of science. Like any other scholarly discipline, the field's primary responsibility must be to itself. Increasing signs of its selective impact on other enterprises may, however, justify brief analysis.

Among the areas to which the history of science relates, the one least likely to be significantly affected is scientific research itself. Advocates of the history of science have occasionally described their field as a rich repository of forgotten ideas and methods, a few of which might well dissolve contemporary scientific dilemmas. When a new concept or theory is successfully deployed in a science, some previously ignored precedent is usually discovered in the earlier literature of the field. It is natural to wonder whether attention to history might not have accelerated the innovation. Almost certainly, however, the answer is no. The quantity of material to be searched, the absence of appropriate indexing categories, and the subtle but usually vast differences between the anticipation and the effective innovation, all combine to suggest that reinvention rather than rediscovery will remain the most efficient source of scientific novelty.

The more likely effects of the history of science on the fields it chronicles are indirect, providing increased understanding of the scientific enterprise itself. Though a clearer grasp of the nature of

scientific development is unlikely to resolve particular puzzles of research, it may well stimulate reconsideration of such matters as science education, administration, and policy. Probably, however, the implicit insights which historical study can produce will first need to be made explicit by the intervention of other disciplines, of which three now seem particularly likely to be effective.

Though the intrusion still evokes more heat than light, the philosophy of science is today the field in which the impact of the history of science is most apparent. Feyerabend, Hanson, Hesse, and Kuhn have all recently insisted on the inappropriateness of the traditional philosopher's ideal image of science, and in search of an alternative they have all drawn heavily from history. Following directions pointed by the classic statements of Norman Campbell and Karl Popper (and sometimes also significantly influenced by Ludwig Wittgenstein), they have at least raised problems that the philosophy of science is no longer likely to ignore. The resolution of those problems is for the future, perhaps for the indefinitely distant future. There is as yet no developed and matured "new philosophy" of science. But already the questioning of older stereotypes, mostly positivistic, is proving a stimulus and release to some practitioners of those newer sciences which have most depended upon explicit canons of scientific method in their search for professional identity.

A second field in which the history of science is likely to have increasing effect is the sociology of science. Ultimately neither the concerns nor the techniques of that field need be historical. But in the present underdeveloped state of their specialty, sociologists of science can well learn from history something about the shape of the enterprise they investigate. The recent writings of Ben-David, Hagstrom, Merton, and others give evidence that they are doing so. Very likely it will be through sociology that the history of science has its primary impact on science policy and administration.

Closely related to the sociology of science (perhaps equivalent to it if the two are properly construed) is a field that, though it scarcely yet exists, is widely described as "the science of science." Its goal, in the words of its leading exponent, Derek Price, is nothing less than "the theoretic analysis of the structure and behavior of science itself," and its techniques are an eclectic combination of the historian's, the sociologist's, and the econometrician's. No one can yet guess to what extent that goal is attainable, but any progress toward it will inevitably and immediately enhance the signifi-

cance both to social scientists and to society of continuing scholarship in the history of science.

## II

## THE PHILOSOPHY OF SCIENCE

The general topic of the philosophy of science can be divided into subareas by subject matter: the philosophy of physics, the philosophy of biology, the philosophy of the social sciences, and so

on. But it may also be divided into discussion of *structural* problems in science, on the one hand, and *substantive* problems within specified sciences, on the other. Structural problems are those traditionally associated with such topics as scientific inference, classification, explanation, prediction, measurement, probability, and determinism. Substantive problems arise when a question is asked such as "How can learning theory be axiomatized?" or "How should anxiety be defined?" Substantive problems, as a class, merge gradually into abstract scientific problems, which are properly handled by scientists themselves.

The substantive philosophy of science usually requires some professional training in the relevant field, whereas the structural philosophy of science may require only a general scientific education. Both require professional training in philosophy or, to be more specific, in logic, broadly conceived (that is, not only in classical or in symbolic logic). The history of science is also of very great importance to the philosopher of science, for it provides him with more numerous and more diverse examples of conceptual schemes and theories than he could ever find in contemporary science, and such schemes and theories are his raw data.

It will be seen, then, that a large part of the philosophy of science stands to scientific theorizing, classifying, and so on, as experimental design stands to scientific experimenting. For the philosophy of science is simply the discussion of general criteria for theories, classifications, and the rest, and is necessary as long as the intuitions or assertions of scientists about what constitutes good procedure are in conflict or might be improved by analysis. Curiously enough, however, many scientists reject the philosophy of science as irrelevant to their own activities, although they constantly talk it and teach it and illustrate its relevance in their work, sometimes under the title "methodology" and sometimes just as advice without a title. It is only the hyperspecialized, rock-ribbed empiricist who can entirely avoid discussing the subject in his scientific work and teaching, and even he usually contradicts himself by espousing operationism as the epitome of empiricism—a rather elementary mistake which would have grave consequences for the validity and utility of his results if he acted on it. Often the antagonism of science to philosophy seems due to a low tolerance of ambiguity, and particularly to insecurity about involvement with the more debatable and less decidable issues of philosophy. This is surely an immature reaction, unless it can be shown that

these issues need not be raised in the teaching and practice of science.

This article will provide (a) a brief discussion of those aspects of the structural philosophy of science which have special relevance for the social sciences and (b) some reference to substantive issues in the philosophy of particular social sciences. In general, these aspects will be intertwined, in order to illustrate the immediate relevance of the structural topics to substantive issues.

**Main concerns of the philosophy of science.** Science has been said to be concerned with observation, description, definition, classification, measurement, experimentation, generalization, explanation, prediction, evaluation, and control of the world. This list is of course much too comprehensive; to be at all useful it has to be narrowed down in the course of examining individual scientific activities (for instance, instead of analyzing description in general, we might ask what *kind* of describing is scientific, as opposed to poetic). In any case, there are as many (though probably no more) points of view about main topics in the philosophy of science as about main topics in any of the sciences. If the area of dispute sometimes appears greater than it is, this is because when a subtopic in philosophy is settled, it is given a new name and called a science. Philosophy is the mother of sciences and has spawned physics, astronomy, symbolic logic, economics, and psychology, among other subjects. The domain of fundamental and still unresolved conceptual disputes at any time is called philosophy and, of course, bears the cross of conflict. But, perhaps for that very reason, it is a residue that eternally regenerates, is perpetually fertile. The social sciences began with a similar handicap; what was well known about human behavior was called common sense, and only the muddy residue was left for psychology and the other social sciences to clarify. It is no wonder that a subject is difficult and debatable when it is defined to exclude the easy and certain.

Because "science" is a term for an activity as well as for a body of knowledge, we ought not to be surprised if it is continuous with the prescientific activities directed to the same ends, and if these, in turn, are an extension of prelinguistic adaptive behavior. This synoptic view of man's cognitive development and current equipment should—and, I believe, does—provide some criteria for good scientific practice. We can begin by applying it to the various procedures connected with scientific concept formation: observation, description, definition, and classification, with meas-

urement and generalization as closely related activities.

**Concept clarification.** It is now widely accepted in the philosophy of science that we must qualify or reject the traditional idea that the basic data from which the scientist forms his hypotheses and classifications are provided by a faculty of observation which is somehow independent of science. Not only has the attempt by sense-data theorists and phenomenologists to identify these basic data been a total failure, but the failure begins to appear explicable. We have come to see the "observation language"—the nonscientific language in which such basic data were supposed to be reported—as really just a "theory language," with somewhat higher interjudge reliability than more abstract language, yet still subject to perceptual errors in its application and even to pervasive errors caused by infiltration by unnoticed theory. When errors of the latter kind are recognized, we may redescribe our observations or we may retain the old language and simply reinterpret it, perhaps metaphysically. Thus Feyerabend has pointed out (in conversation with the author) that the expression "The sun is rising," although it originally incorporated a false astronomical theory, has been retained as a statement of pure observation. So there is no absolutely basic observation level on which all theory rests and, even more clearly, no sharp distinction between observation and theories. We must think instead of a constant interaction and exchange between observation, which seems immune from correction, and speculative theory. Indeed, the development of new instruments may simply render observable the hitherto unobservable (as when the electron microscope was developed) or the observed mistaken (as when it became possible to measure the curvature of the seemingly flat earth). Does this relativization of the distinction between observation and theory destroy the distinction's utility? Not at all. Indeed, it strengthens our understanding of the hierarchical structure of science as a whole when we realize that observables of the  $n$ th level (for instance, in neurophysiology) may include some hypothetical constructs from the  $(n + 1)$ th level (in this case, individual psychology).

What leads us, then, to introduce concepts at a given level? Not just the pressure of their existence on our blank brain. Rather, the preconscious selective effect of certain environmental and internal pressures began the process of concept formation in our ancestors, as in other organisms—a sequence of events that can be summarized as "dis-

crimination under drive conditions." The preverbal organism comes to react to certain stimulus configurations that represent ingestibles or predators, and it is simply an extension of this process when an interpersonal vocabulary is introduced to refer to these configurations. The psychologist refers to both the preverbal and the verbal stages of this process as concept formation, and although many philosophers prefer to restrict the term to the verbal stage, there is no doubt that the verbal stage develops from the preverbal one, whether or not it becomes qualitatively different in the course of development. [See CONCEPT FORMATION.]

**Definition.** Given the pragmatic view of concept formation outlined above, it is very natural to abandon classical definition theory (in which a definition is a set of logically necessary and sufficient conditions for the use of a term) and to adopt instead an approach based on the notions of indicator and of indicator clusters. The rationale for such an approach may be stated as follows. Within a formal system, such as mathematics or an invented language, we can find examples of classical definitions, but seldom, if ever, can we find them within a natural language or the language of a developing science. The reason for this is simply that natural phenomena are extremely untidy, and a language for referring to them must be flexible enough to accommodate this untidiness if it is to be scientifically useful. For instance, the concepts "subject," "length," "response," "group," "aggression," and "temperature" cannot be given classical definitions (other than trivially circular ones). But we have no serious difficulty in learning or teaching these concepts, which we do by giving paradigm examples, contrasts, and explicitly approximate or conditional definitions. Any paradigm provides us, if it can be successfully analyzed, with a set of sufficient conditions for the application of the term, but it is not possible to insist that paradigms, let alone analysis of them, can never turn out to be erroneous. So the sense in which these conditions are sufficient is still not that of logical sufficiency. It is still more obvious that we often cannot specify any properties that are logically necessary for the application of the concept. We therefore adopt the notion of "weighted indicators," or criteria—that is, properties which are relevant to the application of the term, but in varying degrees. Some of the properties may, in some cases, be virtually necessary, some small groups of them may be sufficient; but these are special cases. The clustering of these properties in property space indicates an entity for which it is useful to have

a name, but there is typically considerable scatter and no sharp boundary to the cluster (the so-called open texture of concepts). The charm of a concise translation (that is, of a classical definition) is not often provided by the cluster approach, but it does preserve that most valuable feature of classical theory—a reliable verbal response that can be successfully taught. Contrasting and approximating, which are the other procedures involved in specification of meaning, depend on the psychological superiority of discrimination skills over absolute recognition skills and involve no new logical points.

At this point, it should be stressed that there are two elements in the theory of definition: the pragmatic and the literal. We have been talking about the limitations of the literal theory of definition as a kind of translation. But there is the independent question of how one can best—that is, most usefully—select the terms that one will mention in the definition, whether it is a translation or a cluster of indicators. A famous answer to this has often been taken as both literal and pragmatic, which makes it nonsensical instead of good pragmatic advice of a limited range of applicability. I refer to operationism (for which see especially Bridgman 1927). There are, of course, some areas where it is to be taken very seriously as advice, and psychology is one of them. (In theoretical physics, contrary to the common impression, it is extremely rare to seek or find operational definitions.) But if operationism is taken as requiring that definitions actually contain nothing but operations, then it is absurd, a category error—and, in addition, it is self-refuting, since the concept of an operation cannot be defined operationally. Definitions should therefore be of such a kind that we can apply some independently determinable criteria to decide when the defined term should be used (we can, if we wish, call the process of determining whether these criteria apply “operations”). But we cannot require that the only content of definitions should be operations, or we find ourselves caught in the dilemma of deciding when we have only one operation and, hence, only one concept . . . and so on.

**Classification.** The traditional requirements for classification also need to be relaxed. Instead of the Aristotelian requirement of exclusive and exhaustive subcategories, we must settle for minimized overlap and maximized coverage, balancing these desiderata against considerations of simplicity and applicability. The development of a scientific classification scheme is essentially a remapping of property space, using a new system of

coordinates or a new projection. Hence, assessment of the scheme's value very much depends, as in the map analogy, on the purposes for which it is intended (which may be as diverse as fast labeling, representation of a new theoretical insight, and easy recall) and very little on the idealized and context-free notion of “cutting Nature at the joints,” which was the goal of earlier taxonomists (and which still admirably expresses the feeling inspired by a successful classification scheme).

**Measurement.** The urge to measure is a kind of conditioned reflex among empirically trained scientists, and with some reason. Measurement requires—or, when developed, provides—an inter-subjectively reliable procedure for applying the potentially infinite descriptive vocabulary of number. For describing any continuous variable we need such a vocabulary, and for describing many discrete variables it is exceedingly useful because it creates the possibility of applying some mathematical apparatus. But the social scientist all too often assumes that scaling and measuring will make it likely that we can discover useful laws. In fact, many scales disguise the existence of regularities, and many others fail to reveal them. The descriptive utility of a scale must be considered independently of its theoretical fertility, for the two considerations may lead in different directions. The proliferation of scales, like the proliferation of statistical analyses, often merely clogs the channels of communication. There is no magic about numbers *per se*, and only hard thinking and good fortune, in combination, achieve a worthwhile new scale. The same is true of classification. The cluster concept is peculiarly suited to the needs of statistical scaling and to those of statistical inference in general. [See CLUSTERING; SCALING.]

**Evaluation.** The notion of measurement phases quite gradually into that of evaluation. “Pecking order,” “peer-group ranking,” and “intelligence quotient” can all, in certain contexts, appear as value-impregnated scales. This is often disputed by those who think “value” is a dirty word. Social scientists are peculiarly susceptible to the charms of the Weberian myth of a value-free social science, which rests on a one-sided interpretation of the distinction between facts and values. In its more defensible form this distinction amounts to the assertion that (a) evaluation depends on establishing certain facts; and (b) evaluation goes beyond the facts on which it depends. To this it can be objected that evaluation may well *result* in facts, albeit facts different from those with which it begins.

Thus *Consumer Reports* can often substantiate

evaluations such as "Brand X is the best dishwasher on the market today" on the basis of performance data plus data about the consumers' wants. And that evaluation, when suitably supported, simply states a fact about Brand X. It is one thing to be cautious about importing *dubious* value premises into an argument; it is another to suppose that all value premises or conclusions are dubious, "mere matters of opinion." It is not at all dubious that dishwashers should get the dishes clean, that clocks should keep good time, and so on. It may simply be a fact that Brand X of dishwasher excels at its task. Since the evaluation is nothing more than a combination of these facts, it is itself a fact, although it is also an evaluation.

Precisely this analysis applies to myriad issues in the social sciences—evaluation of the relative merits of protective tariff barriers and direct subsidies or of different forms of treatment for dysfunctional neurosis, to name only two examples. Of course, there are many other issues where only a relativized answer is possible, since legitimate differences of taste exist (that is, differences where no argument can establish the superiority of any particular taste). But this in no way distinguishes evaluation from theoretical interpretation. It will not do to say that "in principle" these differences can be resolved in the theoretical area when more facts are available, but not in the evaluation area. Not only are there very fundamental disagreements about the function of theory that make this improbable, but additional facts often reduce value disagreement. In any case, *relativized* answers, which are still value judgments, admit of no disagreement, and therefore do not involve subjectivity. It is simply naive to suppose that fields must, if they are to be regarded as objective, always contain answers to questions of the form "Which is the best X?" Neither mathematics nor engineering has this property, or any corresponding property with respect to "Which is the true solution to X?" where the conditions of X are incompletely specified.

As to the final defense of the distinction between fact and value—that a particular choice of ultimate values, or ends, cannot be proved true—three answers apply: (1) No such choice has to be proved true, only relevant. (2) No one has yet produced a demonstrably ultimate value, and it seems clear that the hierarchical model is as inappropriate here as it is in epistemology. (There are no ultimate, or basic, facts, only some that are more reliable than others; and all can—under pressure—be given support by appeal to others.) (3) In the case of moral values, where some need for a single

answer can be demonstrated, there is a perfectly good way of handling any moral disputes that are likely to arise in the social sciences. This is by appealing to the equality of *prima-facie* rights—the fundamental axiom of democracy. Justification of this is itself one of the most important tasks of the social sciences and requires contributions from game theory, political science, economics, sociology, and psychology, as well as from the obvious candidate, anthropology. It is the problem of deciding on the best system of sublegal mores—insofar, of course, as any answer is possible. But this *type* of problem is already familiar: it is an efficiency problem.

Indeed, the social sciences have for too long been reticent about pointing out the extent to which it is possible both to give answers to moral problems and to refute some of the current answers to them. For some reason, the sound point that there are many areas of morality where there cannot yet be any proof of the superiority of a particular answer is taken to imply that acting as if any answer were correct is defensible. But of course the only defensible position in such a situation is a compromise or, if possible, a suspension of action. In my opinion, the axiom of equal *prima-facie* rights can be shown to be superior to any alternative, and also to be capable of generating a complete moral system. It achieves both of these ends by being the only such axiom that can be satisfactorily supported, and of course it roughly coincides with the Golden Rule and other basic maxims (details of this line of argument will be found in Scriven 1966). At any rate, it is time that the possibility of this kind of "strategic ethics" was examined by all the strategists who have sprung up to look at other kinds of social interaction in terms of the language of games.

In summary, the scientific approach to evaluation necessarily involves both applied science (finding the best solution to a practical problem) and pure science (finding the best estimate, hypothesis, or experimental design). Moreover, the element of evaluation enters into much "straight" measurement—that of intelligence, creativity, and social acceptability, for instance. The reason for this is as simple as the reason for introducing new classifications: we have to order our knowledge if we are to use it efficiently. It follows that the most appropriate kind of order is determined by the use to which that knowledge is to be put. One might put the point paradoxically and say that all science is applied science. The application may be to efficient explanation, accurate prediction, or improvement of the world, but it is still—in one important

sense—an application. Nor can we assess (that is, evaluate) theories or instruments unless we have some analysis of their proposed use.

**Data analysis.** There are obviously limitations on the memory storage capacity of the human brain that would make it impotent in the face of even a modest amount of data about the path of a projectile or a planet, if these data were presented in discrete form. But if we can find some simple pattern that the data follow, especially if it is a pattern that we are familiar with from some other, preferably visual, experience, then we can handle it quite easily. (The preference for visual models is due to the vastly greater channel capacity of the visual modality; the notion of "handling" involves more than simple recovery, and even that involves more than storage capacity, since it includes look-up and read-out time.) This simple point can be taken as the start for a complete data-processing approach to the aspects of structural philosophy of science that remain to be discussed. It also pervades the parts already discussed, for the introduction of concepts is itself a device to cope with the "buzzing, blooming confusion" of sense experience.

**Generalizations and laws.** The simplest examples of the cognitive condensation described in the preceding section are laws and generalizations. They are so necessary that we are prepared to forgive them a very high degree of inaccuracy if only they will simplify the range of possibilities for us. Contrary to Karl Popper's view, which stresses the equivalence of a law to the denial of counterinstances, the present view suggests that we are rightly very unimpressed by counterinstances in this irregular world, and extremely thankful if we can find a regularity that provides a reasonable approximation over a good range of instances. This is as true in the physical sciences as in the social, for the laws of gases, the laws of motion, gravitation, radiation, and so on, are all merely approximations at best. There are occasional exceptions (for example, the third law of thermodynamics), but the important feature of a law is that it introduces a pattern where none was before. In this sense its truth is its utility, not its lack of error. A great deal has been made in the literature of the fact that a law will support counterfactual inferences while an accidental generalization will not (Nagel 1961, pp. 68–73; compare Strawson 1952, pp. 85, 197, 200). On the present view, all this means is that we think natural laws are true of continuing or pervasive phenomena, i.e., of the nature of things. All other attempts to give logical analyses of the concept of law—for instance,

the view that laws cannot contain reference to particular entities, or must support predictions—seem to me simply arbitrary.

**Explanation.** The task of explanation is the integration of "new" phenomena (whether subjectively or objectively new makes no difference) into the structure of knowledge. Typically, this consists in fitting these phenomena into a pattern with which we are already familiar. But explanation is not simply reduction to the familiar. Indeed, it may involve reducing the familiar to the unfamiliar, as Popper (1963, p. 63) has pointed out. But it must involve reducing the uncomprehended phenomenon to phenomena that are comprehended, and it is hardly surprising if this sometimes increases the sense of familiarity.

It has long been argued that the way in which explanation is performed in science always involves subsuming the phenomenon to be explained under a known law [see SCIENTIFIC EXPLANATION]. In view of the known deficiencies in our scientific laws, explanation, if this theory were acceptable, would in any case be a rather imprecise affair. But the restriction to laws is too confining, unless one treats the term "law" so loosely that it covers almost any statement except a pure particular. The real danger in this model of explanation—the "deductive" model, as it is usually called—is that it seems to support the view that explanations are closely related to predictions. In contrast, the "pattern" model of explanation, which I prefer, allows for retrospectively applicable patterns as well as for those which can be grasped in advance of their completion. It happens that this is very important in the behavioral sciences, since there is, and always will be, a real shortage of "two-way" laws (that is, laws that both predict and explain). This has typically been treated by social scientists as a sign of the immaturity of their subject; but in fact it is simply a sign of its nature and is very like the situation in the "messier" areas of the physical sciences, especially engineering. When a bridge fails, or a mob riots, or a patient commits suicide, there are often a number of possible explanations, of which only one "fits the facts." We thus have no difficulty in saying that this one is *the* explanation, although the facts available before the event were not enough to permit us to tell what would happen. Indeed, it may be that the chances in advance were very strongly against the actual outcome, and that we would therefore have been entitled to make a well-founded scientific prediction of the event's nonoccurrence. It is not helpful to suggest in such cases that we are explaining by deduction from a law. What sort of

law? That some factors *can* cause others? That *only* certain factors cause a certain effect? These are indeed general propositions, but they do not look much like laws of the usual kind, and they do not support any predictions at all. It is not in the least important whether or not we call them laws, but it is important to understand that we often support explanations by appealing to general claims that will not support predictions.

**Prediction.** On the other hand, it is often possible to predict on the basis of laws that do not explain. Any reliable correlation, however little we understand it, will give us a basis for predicting (that is, of course, provided there is temporal separation between the two correlated factors). To be able to predict, we need only to be able to infer that an event must occur at some conveniently remote time in the future. To explain, on the other hand, we have only to show *why* something occurred, not necessarily that it *had* to occur.

For a long time it was thought that the only way we could be sure to avoid *ad hoc* explanations was to require that (a) the grounds for the explanation be known to be true and (b) these same grounds imply only one possible outcome, the event or phenomenon to be explained. But there are many ways in which we can show that a particular explanation is correct in a particular case without having to show that the factors mentioned in the explanation would enable one to infer the explained event.

For example, we may demonstrate the presence and operation of a particular cause by exhibiting some clues that uniquely identify its *modus operandi*. Of course, we may still have reason to believe that there are certain other factors present which, in conjunction with the factors we have identified, would enable us to make a formal inference that the event we have explained was bound to occur. But in many cases we do not know what those other factors are, and we do not know the laws that would make the inference possible. In fact, our belief that we may still be able to make this inference merely indicates that we believe in determinism. It certainly does not prove that a good scientific explanation demonstrates the necessity of what it explains.

No doubt it is tempting to remark that a *complete* explanation would have this property, but even this approach is wrong. In the first place, there are many so-called complete scientific explanations that do not have it. Second, this approach recommends a use of the term "complete explanation" that has the unpromising property of identifying mere subsumption under a generaliza-

tion as complete explanation. But the genius of Freud, for instance, was not manifested by proving that the "explanation" of obsessive behavior in a particular neurotic was that this behavior was common in neurotics. Rather, he claimed to show a causal connection between certain other factors and obsessive behavior; and a causal connection is neither as strong nor as weak as a high correlation, it is simply quite different.

**Causes.** We are often able to identify causes in the social sciences without being able to give the laws and other factors in conjunction with which they operate to bring about their effects. The basic control group study is a case in point. It may give us excellent grounds for supposing, let us say, that a particular drug accelerates the subjects' rate of response, but it does not tell us what other factors are necessary conditions for this effect. Of course, we know that it is some set of the factors which are present, but we do not know which set. In more complex cases, even though a particular factor does not reliably lead to this effect, we may establish it as the cause simply by elimination of the alternative possible causes, either through their absence or through the presence of clues showing that, although present, they could not have been active this time. Of course, causal explanations are incomplete in the sense that there are always further interesting questions about the phenomenon that we would like answered. But this is also true even when we can subsume the explanation under a law: for instance, we can ask why the law is true. But causal explanations are often complete in the sense that they tell us exactly what we need to know, for our interest in a phenomenon is often very specific. Thus explanation is a context-dependent notion; explanations are devices for filling in our understanding, and the notion of *the* explanation makes sense only when there is a standard background of knowledge and understanding, as in the normal pedagogical development of an academic subject.

**Understanding.** The key notion behind that of explanation, and hence that of cause, is understanding. It must not be thought of purely as a subjective feeling; the feeling is only something associated with it. The condition of understanding itself is an objectively testable one; in fact, it regularly is tested by examinations, which are supposed to stress the detection of "real understanding," not just rote knowledge. Understanding is integrated, related knowledge; more generally — so that the definition will apply to the understanding possessed by machines, animals, and children — it is the capacity to produce the appropriate re-

sponse to novel stimuli within a certain range or field. It is a characteristic of tests for understanding that they present the student with new problems, and the possession of understanding is valuable just because it does embody this capacity to handle novelty.

Approaching it in this way, we see immediately that the question of how the brain can provide this capacity is of interest not only from a neurophysiological point of view but possibly also as a way of obtaining better insight into the nature of understanding itself. In fact, a remarkable overlap emerges between the requirements of efficient storage and understanding, as it is commonly conceived. Efficient storage, both to economize on storage capacity and to facilitate fast recovery and input, must use mapping, modeling, and simplifying procedures. But these are exactly what we use in the process of trying to understand phenomena, even in the more pragmatic process of trying to improve our classifications, descriptions, and predictions. Thus, to mention one example of how fruitful this conception is, the idea of simplicity, which has often been recognized as a criterion for satisfactory scientific theories, can be seen as equivalent to the familiar notion of economy, not as some mysterious aesthetic requirement. Nor is the whole aim of understanding to be seen as a concession to human weakness; for the most sophisticated and capacious computers we shall ever design will be hard pressed to store even part of the brain's data and will therefore have to employ procedures that economize on storage space. Putting the matter more strongly, a simple map stores an infinity of facts with very little complication in the read-out procedures, in comparison with list storage, and an enormous improvement in speed of readout (that is, of recall); it also handles a quantity of information that would be beyond the capacity of ordinary list storage. (The difference between the use of models and the use of mnemonics is that the model stores an indefinite number of facts, which the mnemonic does not, and the model stores them in a way that is more directly related to truth.) Models, from analogies to axiomatizations, are the key to understanding. [See VERSTEHEN.]

Experimentation. The use of applied science for the purpose of controlling reality has its counterpart within the methodology of science itself in the area of experimentation. Thus applied science is to pure science as experimentation is to pure observation. In each case the armory of relevant methods is importantly different: the "purer" subjects are more concerned with understanding and

description; the more applied ones, with causation and manipulation. Indeed, it does not appear possible to give an analysis of "cause" without some reference to manipulation, though a great deal can be said before coming to the irreducible element of intervention or action. [See CAUSATION.]

A number of topics have not been discussed here, although they are closely related. For example, the problem of the reduction of one science or theory to another is a combination of a problem about explanation with one about definition. I have also said very little, even implicitly, about the issue of free will versus determinism, and wish only to state that it now seems possible to reconcile the two positions, provided we first make a distinction between predictive and explanatory determinism. In conclusion, I should stress my conviction that there is very little in the social sciences that does not have a parallel in the physical sciences, but it has not been to these parallels that social scientists have turned for paradigms. They have turned instead to the absurdly oversimple paradigms of Newtonian mechanics and astronomy. Even there, the significant fact is that the problem of predicting the motion of pure point-masses, moving under the sole influence of the very simple force of gravity, passes from the realm where solutions and predictions are possible to the realm where solutions give way to (at best) explanations as soon as the number of bodies is increased from two to three. It is surely absurd to imagine that the forces acting on human beings are simpler than those involved in the "three-body problem." And if this is so, then we need a new "methodology of the complex domain," perhaps along the lines indicated above.

#### BIBLIOGRAPHY

*Contemporary philosophers of science can be roughly classified as either post-positivists (who form the majority) or linguistic analysts. For examples of work by leading post-positivists, see Popper 1934, 1957; Carnap 1950, Reichenbach 1951; Hempel 1952; 1965; Braithwaite 1953; Nagel 1961; Feyerabend 1962; Kemeny & Snell 1962; Suppes & Zinnes 1963. There are many important topics on which*

these authors disagree, but it seems fair to say that among the predecessors they would be prepared to acknowledge are such founders of modern positivism as Karl Pearson, Moritz Schlick, and Ernst Mach. Other outstanding earlier writers who, although somewhat untypical of the field, have contributed to the philosophy of science in general, not just the post-positivist branch of it, include C. S. Peirce, Max Weber, N. R. Campbell, P. W. Bridgman, and Harold Jeffreys. Works by philosophers of science who use at least some of the methods of the linguistic analysts, even if they would not all classify themselves as such, include, in the study of the physical sciences, Toulmin 1953; Polanyi 1958; in the study of the social sciences, Dray 1957; Winch 1958; Kaplan 1964; Scriven 1966; and, in the field of measurement and probability, Ellis 1966; Hacking 1965. Certain trends in the history of science, particularly in the emphasis, developed in Butterfield 1950 and Kuhn 1962, and by Alexandre Koyré, on autonomous conceptual schemes as units of progress, have influenced the philosophy of science. These trends have in turn been influenced by philosophical works such as Feyerabend 1962; Hesse 1963. Among the extremely valuable contributions to the philosophy of science made by practicing social scientists, special note should be taken of Simon 1947-1956; Skinner 1953; Meehl 1954; Stevens 1958; Chomsky 1966. Of the general treatises available in 1966, only McEwen 1963 and Kaplan 1964 are concerned principally with the social sciences, although Nagel 1961 and Hempel 1965 deal with them to some extent. Lazarsfeld 1954; Natanson 1963; Braybrooke 1966 are interesting collections that focus exclusively on the social sciences. As an introduction to the philosophical problems of the social sciences, Kaplan 1964 is to be recommended to layman and expert alike, although the work takes an approach somewhat different from that presented in this article.

## III

## THE SOCIOLOGY OF SCIENCE

If the sociology of knowledge is defined as the part of sociology that studies the nature of and relations between different types of idea systems, on the one side, and the relations between these idea systems and a variety of institutional (or social-structural) and personality factors, on the other, then the sociology of science is one part of the sociology of knowledge. It is the part that specializes in defining the nature of scientific ideas and in describing their relations both to other kinds of ideas (e.g., ideological, philosophical, aesthetic, religious) and to various institutional and personality factors. Parsons (1951, especially chapter 8) has given us what is still the best analytic definition of idea systems in general and their several specialized subtypes, although further analysis and operational specification of his classification are necessary.

The sociology of science, as is the case with all sociology, general or special, is primarily interested in the construction of a set of highly generalized, systematic, and relatively exhaustive concepts and propositions of relationship. In this enterprise it uses data from all historical periods and all cultures, since its main concern is not with history as such, but with establishing sociological concepts and propositions. The history of science, although it always should use such explicit sociological concepts and propositions, often does not, preferring

its traditional, less examined, and frequently common-sense ways of treating its materials. In either case, the history of science, both advertently and inadvertently, may be productive of materials or even of new concepts and propositions for the sociology of science, but this is not its essential task. Thus, the sociology of science and the history of science overlap but do not coincide.

The sociology of science, finally, is interested both in fundamental scientific ideas themselves and in the application of these fundamental ideas, or of more empirical ideas, to technology. In its study of technology, again, the sociology of science uses both historical and contemporary data, drawn from a variety of cultures, regardless of the original purpose for which these data were collected, so long as they serve its primary goal of constructing a system of analytic concepts and propositions.

The social nature of science. One of the basic working assumptions of structural-functional theory in sociology is that man's behavior in society is a response to certain functional problems that he confronts in his nonsocial and social environments. On this assumption, sociology sees man's scientific behavior as his response to the functional problem created by his need to have adequate adjustive knowledge of the physical, biological, and social aspects of the empirical world. Such knowledge is indispensable for some form of adjustment to that world in its three essential and different aspects. Everywhere, as archeology, ethnology, history, and sociology have severally demonstrated, man in society has a certain amount of this scientific knowledge. The amount, of course, varies a great deal among societies. In other words, science, as Malinowski recognized (1916-1941), is a matter of degree, with some societies having only a relatively small amount and others having a great deal more. This, indeed, sets some of the essential problems for the sociology of science. For it is not only the universal occurrence of at least a small amount of scientific knowledge, but also the patterns of variation in the degree of development of such knowledge in different societies, and variations at different stages in the evolution of a single society, that the sociology of science has undertaken to explain.

In order to explain the degree of development of science considered as a complex whole, it is necessary to distinguish its component cultural, social, and psychological parts, for each of these can develop at somewhat different rates in different social situations. It is useful to define at least four general components of science as a whole,

each of which has a measure of autonomy: substantive scientific ideas; scientific methodology, including both ideas and instruments; scientific roles; and motivational and reward systems for scientific roles. Let us consider, again because this sets important problems that the sociology of science has been trying to explain, how each of the components varies along certain dimensions.

Substantive scientific ideas vary along three dimensions: of generality, or abstractness, as it is also often called; of systematization; and of exhaustiveness for the relevant aspects of the phenomena. We may say that the more abstract, the more systematic, and the more nearly exhaustive a set of substantive scientific ideas is, the greater the degree of its scientific development. Among the interesting problems that the sociology of science tries to explain is the question of why the physical sciences on the whole have developed more rapidly in all three respects than have the biological sciences and why these, in turn, have developed more rapidly than the social sciences. Within each of these broad sectors of science, moreover, further variation in the degree of development of specialized subspecies poses similar problems for explanation. For example, the more rapid recent development of economics than of political science or sociology can be explained, in part, by the greater accessibility of data on price phenomena than of data on people's political and social norms and actual behavior. This greater accessibility is due, in turn, and again in part, to the more pressing felt needs that governments and business firms have for price data.

Knowledge about the ideas and instruments (or technology) that make up scientific methodology also varies in its degree of development. It is clear that modern science has made great advances over earlier science in the sophistication of its knowledge about such essential methodological matters as the character of concepts and classifications, the logic of comparison and inference, and the functions of contrived and natural experimentation. Modern science is also at a great advantage over earlier science in the degree of its access to ordering and measuring facilities. Mathematics is, of course, the most important of such facilities, and its development has been of very great moment in the closely related development of all the sciences, although, again, to varying degrees among the several sciences, for interesting sociological reasons. In addition to mathematics, such instruments as thermometers, high-speed electronic computers, and a thousand others have contributed significantly to the advances of the sciences. Both

the development of these measuring facilities and their adoption by the several sciences are important focuses for research in the sociology of science. Since they may develop sometimes as a direct result of changes in scientific ideas, but also sometimes independently, methodological ideas and instruments have various types of relationships with substantive scientific ideas. When they develop to some extent independently, as in the cases of the telescope or the computer, for example, methodological ideas and instruments may at certain times play the leading part in the development of a whole sector or subsector of science. Or again, it is an important sociological fact about the prospects of the social sciences that their ability to borrow a great deal of the methodological sophistication developed in the other sectors of science is a key asset for their own development.

There is also considerable variation among societies in the degree of differentiation and specialization of social roles for engaging in the many types of scientific behavior, in the proportion of members of the society engaged in these roles, in the kinds and amounts of support given to these roles, and in the degree of institutionalization of scientific roles. The sociology of science has been much concerned with these essential problems of the social organization or role component of science, so much so that we shall take them up below, in a separate and detailed discussion.

Finally, motivational and reward systems for scientific roles also vary among and within societies. They differ in the type of rewards, in the strength of motivation, and in the degree of diffusion of adequate incentives throughout the population as a whole. Again, we shall consider this matter more fully below.

### The development of science

Viewed in the long perspective, science shows a history of continuity and cumulation from the earliest prehistory of man to the present. However, this history has been marked by quite different rates of development in different times and places. It is this unevenness in its progress, viewed in terms of shorter perspectives, that calls for explanation by the sociology of science. As the sociology of science has itself made progress, a few basic principles of explanation have come to appear sound. One is the principle that no single cultural, social, or psychological factor, such as religion or economic forces, can account for the growth of science as a whole or any of its several components or subspecies. Another such principle

is that not even any single combination of factors, such as the religious and the economic, or the political and the educational, is sufficient for the tasks of the sociology of science. This is not to say that there are not some combinations of factors more favorable than others for certain kinds of specific development in science, as our discussion of the Protestant ethic will illustrate. There definitely are such favorable combinations, and the sociology of science has improved its ability to discover them by accepting the principle that certain types and rates of development may come from one set of factors (or one set of values of these factors taken as variables) and that other types and rates may come from a different set of factors (or a different set of variables-values).

The following discussion will consider some of the major factors that affect the development of science. They exert their influence on science *always* in combination, and the relative weight of the influence of each may vary in different specific instances.

**Structural and cultural differentiation.** The greater the degree of structural differentiation in a society, that is, of the specialization of roles between the major institutional sectors and within them as well, the more favorable the situation for the development of science. Greater structural differentiation provides the necessary situation not only for a variety of highly specialized scientific roles but also for their highly specialized ancillary and supporting roles in other institutional sectors.

Besides role differentiation, differentiation within culture, that is, in the various systems of ideas in society, is also favorable to the development of science. For example, as Charles Gillispie (1960) has shown, the development of what he calls "the edge of objectivity" of scientific ideas has increased as these ideas have progressively been differentiated from moral ideas about man's place in the universe. The more that values, ideologies, aesthetic ideas, and philosophical ideas are distinguished both from one another and from substantive scientific ideas, the easier it is to see the special problems of each and to develop each and all of them.

**Value systems.** Certain values which the modern world tends to take for granted, but which have not existed in many past societies, certainly in nothing like the same degree, are much more favorable to the development of science than are their opposites. The high value the modern world puts on rationality as against traditionalism, on this-worldly activities as against other-worldly activities, on libertarianism as against authoritarianism, on active striving as against passive adapta-

tion to the world, and on equality as against inequality—all these values support the development of the several components of science. Sometimes the support is direct, as in the case of the values of rationality and this-worldly interest, values which are especially powerful in combination, as they are in the modern world. Libertarianism is essential for academic freedom, which is one kind of important foundation for scientific progress. Sometimes the support from values is indirect, as when the value of equality increases the amount of social mobility and thus helps to select better talent for scientific roles.

**Instrumental needs.** Scientific knowledge is power, that is, power to adjust more or less satisfactorily to the nonsocial environment and to the internal and external social environment. Some scientific discovery and technological innovation, then, is a response to immediate instrumental needs for adjustment to what are defined as dangerous and harsh environments. Certainly this must have been an especially large influence on the development of science in the early stages of human society, when every bit of scientific knowledge was of great instrumental importance in a threatening and severe physical and social environment. But even powerful modern industrial societies respond strongly to their instrumental needs for science. Whatever their values in regard to science, they feel an urgent need to use it to strengthen their national defense, promote industrial and agricultural growth, and improve the health of their populations. Some scientists deplore this "exploitation" of science, that is, this encouragement of science "not for science's own sake." But the instrumental needs of even already powerful societies are defined by their citizens as more important under some circumstances than the value considerations that are preferred by scientists and by those who share the values that support science directly. Finally, the nonindustrial or underdeveloped societies of the present also push the acquisition of science for urgent instrumental needs, to cope with "the revolution of rising expectations" in their populations.

**Economic factors.** A variety of economic structures, needs, and resources, often combined with one or more other social factors, have had very large direct and indirect influences on the development of science. There is no blinking this fact, no matter how much some scientists may think it stains the "purity" of science and regardless of whether one thinks some Marxist sociologists of science have exaggerated it. Only a few of the myriad effects of economic activities on science

can be given in illustration here. As Merton has shown (1936; 1939), in the case of seventeenth-century England, for example, the growing maritime interests, both commercial and naval shipping, were in need of more reliable techniques of navigation. The existing techniques included neither good chronometers nor any sure way of determining longitude at sea. These economic and military-political needs were a direct stimulus, through prizes offered for discoveries and inventions, to basic discoveries in astronomy and on the nature of the spring. Or again, earlier, in sixteenth-century Europe, economic needs for more powerful methods of pumping water out of mines than were provided by the existing Archimedean screw pumps led to work by Evangelista Torricelli and Vincenzo Viviani on the relations between atmospheric pressure and water level. On the basis of this work, successful suction pumps for industrial use were constructed. But this scientific work also led to the invention of the barometer by Torricelli, to the creation of a vacuum by Otto von Guericke, and to a whole host of scientific experiments and results with the so-called "air pump" by Robert Boyle and his colleagues in the newly founded Royal Society. This example shows how economic needs, science, and technology affect each other in complex and often mutually beneficial ways.

In the modern world, both industrial organizations and governments in all societies have provided many kinds of support for science in order to pursue economic interests and needs. Direct support exists in the form of governmental and industrial research laboratories; indirect support is given through tax provisions and other subsidies to both the universities and industry. One of the largest areas of governmental response to economic needs has been agricultural research, which is largely biological research but also includes the physical and social sciences. It should be noted that both "capitalist" and "socialist" societies and both "planning" and "nonplanning" societies have supported science through their responsiveness to the economic interests of special groups in the society and of society as a whole. The desirability of using science to meet economic needs and increase economic resources is no longer anywhere in question among the societies of the modern world.

**Political structures and needs.** Political and economic factors have often tended to be closely combined in their effects on science. Of course, the political factor has also had a great influence on science separately, for example, because of the military needs that governments have had. After the recent history of the part that governments have

played in the development of atomic science for politico-military needs, this point hardly needs further illustration. But this connection between politico-military needs and science is far from new. Governments have always sought to increase military firepower through the development of science. Research on the nature of metals, on the causes of chemical reactions and explosions, and on the mathematics of the curves of ballistic missiles has been spurred by military needs.

**Religion.** Values and religion are closely connected in every society. A religion that supports modern values, which in turn favor science, is, of course, a strong support for the development of science. This specific connection is what Merton has sought to demonstrate in his analysis of the relations between the complex of values and religious beliefs that constitute the Protestant ethic, on the one hand, and the great development of seventeenth-century English science (1936; 1939). The values and beliefs of the Protestant ethic have now been secularized and diffused to many social milieus other than the ones in which they originally arose. In their secular form they are even more powerful supports for the development of science. The relations between a religion and science are always, it should be carefully noted, complex and at partial cross purposes. Thus, although the general beliefs and values of the liberal forms of Protestant Christianity have been favorable to the development of science, even these liberal elements have sometimes protested against specific scientific discoveries that have apparently contradicted basic doctrines of their own. Thus, as Gillispie (1951) has shown, some liberal Protestants who still held to the Biblical conceptions of miraculous floods and other catastrophes were opposed to the notion of geological uniformitarianism when this new scientific idea was first developed in the early nineteenth century. And, a little later, as Dupree (1959) and Lurie (1960) have suggested, there was the same kind of resistance for a while to Darwin's discovery of uniformities in the development of man and the other animal species. In analyzing the relations between religion and science, the sociology of science treats them both as complex phenomena and looks for specific connections between their specific components.

**The educational system.** The maintenance and development of science is facilitated by an educational system that is sufficiently specialized for, and sympathetic to, the growing science of its time. For example, as we may learn from Ben-David (1960), new educational institutions developed for that purpose played an essential role in

the development of French science during the early nineteenth century and in Germany a little later. All the modernizing countries of recent times, from Russia to the small and weak African countries, have greatly strengthened their educational systems at all levels because of their desire to improve their science. Before modern times, the universities were not the home of scientific development, which they have since become. As late as "the Great Instauration" of science in seventeenth-century England, the universities were still indifferent or hostile to science, but a variety of other extremely favorable social conditions helped science to flourish. This hostility continued for some time. Now, of course, a university that is hostile or indifferent to science can exist only in a society, or in one of its parts, that is content to remain a scientific backwater.

**Social stratification system.** A system of social stratification that emphasizes the value of equality and that, in fact, realizes a high degree of social mobility for the members of a society seems to be more favorable for the development of science than is the opposite, or closed, type of system. By providing a greater degree of equality for talent, wherever in the society it originates, the open type of system can provide greater resources of talent for manning scientific posts. Of course, if scientific roles are not highly valued, rising talent will go elsewhere, but the two factors in combination—a high value on science and the openness of the channels of social mobility—are very favorable to the development of science. In the modern world, both of these conditions have been realized in ever greater measure in the older industrial societies. And the newly modernizing societies, as Dedijer (1961) has described them, are making great efforts to bring them into being almost overnight.

### Differentiation of the scientific role

In relatively undifferentiated societies, past or contemporary, there are few roles for full-time "intellectuals," as we may roughly characterize all those whose special function is to deal in some kind of idea system. However, as societies become less simple and more structurally differentiated, the role of intellectual enlarges and is occupied by at least a few individuals on a full-time basis and with support from a variety of sources: a religious organization, the political magnates, or inherited wealth. Certainly in Greece by the fifth century B.C., the role of intellectual had emerged and was occupied with great distinction by men who have influenced all subsequent thought—men like Plato and Aristotle. It should be noted, however, that the

ideas with which such intellectuals dealt were relatively much less differentiated than ideas are in the modern world. On the whole, the intellectual still deals alike with religious, scientific, ethical, political, and philosophical ideas; indeed, the term "philosophy" covers all knowledge, all types of ideas. But it is not until the beginnings of the modern world that this further process of differentiation occurs, that is, differentiation between types of ideas, and makes way for the specialized roles dealing wholly or primarily with scientific ideas. This differentiation of the scientific role from other intellectual roles was slow in occurring, even in the modern world. In seventeenth-century England, the new science was still called "the new philosophy." And the oldest scientific society in the United States, founded in 1743 by Benjamin Franklin, among others, was called the American Philosophical Society. So little differentiated was the specialized role of scientist and so few were those who occupied this role, by whatever name and with whatever means of support, that it was not until the nineteenth century that the very term "scientist" was coined (by the Rev. William Whewell, in England in the 1840s).

The process of differentiation of the role of scientist went slowly until the middle of the nineteenth century because of the difficulty of finding sources of support for it in the securely established social organizations and arrangements. Beginning in the sixteenth century, newly founded scientific societies provided various necessary facilities and supports for scientists, but only a handful of full-time jobs. Governments did something more, but still there were very few full-time positions in government museums or research organizations. Some distinguished scientists, men like Franklin and Boyle, supported themselves on inherited or earned wealth. Others worked at nonscientific jobs as well, or alternated between scientific and other activities; such a scientist was Antoine Lavoisier. Very little was done by the universities and colleges of the time, not until the nineteenth century, and in most places only in the latter half of that century, did they open their doors wide to scientists.

Full institutionalization was achieved, then, when universities, various governmental organizations, and many industrial firms recognized their great need for science, and established regular and permanent roles and careers for scientists. In addition, a variety of special research institutes, endowed by foundations, trade associations, and other special interest groups, or sometimes operated by private individuals for profit, provided further and ever more specialized jobs for scientists.

The necessity and the legitimacy of the scientific role were increasingly acknowledged.

One rough measure of the establishment of the scientific role in the modern world is the quantitative increase in the numbers of those who occupy the role. As Derek Price (1963) has shown, during the last 300 to 400 years there has been an exponential growth rate in the number of scientists in the modern world. Starting from very small numbers, to be sure, the rate of growth is such that there has been a doubling of the number of scientists in something like every 10 to 15 years. Because of the nature of exponential growth rates, the recent increase in the number of scientists has been especially large. Price estimates that about 90 per cent of all the scientists who have ever lived are still alive today. Given this growth rate, as well as other reasons, it is small wonder that the place of science in the modern world is not yet as settled as many would like.

There is, unfortunately, no room here to treat some other aspects of the social organization of science. Such matters as patterns of authority, of collaboration, and of careers in scientific work have recently been well studied by Glaser (1964), Hagstrom (1965), and Zuckerman (1965), among others.

### Motivations and rewards for scientists

The mere existence of social roles is not enough for their full institutionalization. Adequate and legitimate motivations in those who occupy the roles, and adequate and legitimate rewards from those who support the roles, must also exist. On the whole, in the modern world, and especially in the societies that modernized early, these motivations and rewards exist in sufficient measure.

What little evidence we have on the motives of working scientists indicates that, as in all other social roles, a variety of motives in different combinations is at work. For example, because the role of scientist now provides considerable stability, security, and prestige, many scientists are motivated in some measure to achieve these goals. Also, because specialization in basic scientific research provides considerable autonomy to the working scientist, many are motivated to achieve the independence and self-control that the role makes possible. In future social-psychological research on motivation for the scientific role, it will be desirable to keep in mind both the multiplicity of motives that can engage the competent scientist and the way in which the nature of his role structures certain typical combinations of motives. It would be interesting to establish the precise role

of much-vaunted "curiosity" in the motivation of scientists. And it would also be desirable to use a typology of different scientific roles, along the lines suggested by Znaniecki (1940), such as theorist, experimenter, synthesizer, and similar functional types, to see if various typical combinations of motives exist in these different scientific specialties.

As for rewards, the scientific role is now given satisfactory measures of such rewards as security, prestige, and money income to attract its fair share of the talented members of modern societies. As compared with those in business occupations, scientists tend to be rewarded with relatively more prestige for professional standing and relatively less money income. Among scientists themselves, and among the lay public to a lesser extent, there has developed a very elaborate set of symbolic rewards for differential prestige bestowed for differential achievement in science. The awarding of titles, prizes, medals, offices, and eponymous distinctions symbolizes the existing hierarchy of differential prestige. A Nobel Prize in any of the four scientific fields in which it is granted is only the best-known of the symbols of scientific achievement.

The reward of prestige in science is given primarily for originality in scientific discovery, but, since it is sometimes difficult to appraise the degree of originality, sheer productivity may carry off the honors. Like other men in other roles, scientists are deeply concerned about the just distribution of rewards for their activities. Despite the norm of humility that prevails among them and that does influence their behavior, they are motivated to achieve credit for being original, just as businessmen are motivated to receive credit for making a profit. As a result of their concern, as Merton (1957) has so well shown, scientists take pride in priority of discovery and often engage in bitter quarrels over claims to priority. In sum, the role of the scientist is subject, as are all social roles, to a structured set of motivations and rewards, some of which are similar to those in other roles and some of which are different. The scientist is in no sense a "selfless" creature above and beyond the influences of his social role.

During the last decade there has occurred the beginning of systematic research on what is called "the image" of the scientist that the public at large and various segments of the whole society, such as youth or the scientists themselves, actually hold. A favorable image of a social role is, of course, an important reward for those who fill it. The evidence accumulated by this research shows, on the whole, that the image of the scientist is a favorable one.

But as Mead and Métraux (1957–1958) and Beardslee and O'Dowd (1961) have shown in their research, there are some negative tones in the picture—a fear and dislike for some of the characteristics and consequences of the scientific role. In short, there is some ambivalence toward scientists. In certain quarters, this admixture of negative feelings has been much deplored, despite the fact that such feelings probably exist for every social role. Because all social roles probably work at least some negative consequences for some people in some situations, it is utopian to expect a wholly positive image for scientists or for those who occupy any other social-role category.

### Communication among scientists

Since one essential ingredient in the development of science is the combination of already existing ideas, effective communication among scientists is an indispensable part of scientific activities. One of the important social inventions in the early modern period in science was the creation of local, national, and international societies and journals as means for the speedier and more general communication of scientific work within the community of scientists. In order to “keep up” in any branch of science, that is, to learn about the new ideas he can use to discover still further new ideas, the working scientist now has to spend a valuable part of his time with the professional journals, carefully studying a few and scanning many others. In addition to reading the journals, scientists communicate at the meetings of professional associations, both formally and informally. Here, too, as science has developed, there has been a proliferation of specialized groups to match the specialized journals and the specialized activities they report. And, finally, through informal visits, letters, telephone calls, and preprint mimeographed materials, scientists strive to maintain the effective communication without which their activities would be slowed down and even stopped.

In his description of the exponential growth rates for different aspects of science, Price (1963) has also shown that there has been a doubling in the number of scientific journals every 10 to 15 years over the last three or four centuries. Because of this large increase, much of it necessary because of the growth of new scientific specialties, there has been some concern among scientists about the possibility of an excess of information; for some scientists, just “keeping up” has become ever more difficult. In response to this felt difficulty, abstracting services have been created and have multiplied, but still the problem of excessive and inefficient

communication is felt to persist. At the present, therefore, various groups of scientists are trying to codify and computerize the processes of what is called “information retrieval” in science. So far they have not had very great success, partly for reasons suggested below. [See INFORMATION STORAGE AND RETRIEVAL.]

The structure and functions of communications processes among scientists present an obvious set of problems for the sociology of science—one on which much remains to be done. One interesting suggestion from general sociological ideas and from the research that has been done by Herbert Menzel (1959) is that scientists themselves sometimes think in terms of too rational a conception of the communication process; that is, they may be expecting too much from the journals and the formal meetings. In addition to these formal, manifest, and planned communication processes in science, there are the informal, latent, and unplanned ones. Scientists cannot always know precisely what they want and merely push a computer button to get it. Often, through “milling around” at meetings, through chance visits, through indirect channels, they get essential information which they can recognize as essential only when they get it. As a journey into emergent novelty, science must use both planned and unplanned patterns of communication. One of the newer and more interesting focuses of research in the sociology of science is the question of the function of each pattern of communication for different scientific needs and the distribution of these patterns among the different social situations in which scientists find themselves. [See DIFFUSION, *article on* INTERPERSONAL INFLUENCE.]

### The processes of scientific discovery

In contrast with an individualistic, “heroic” conception of the processes of scientific discovery that has prevailed in some quarters, though less now than formerly, the sociology of science has sought to redress the balance of our understanding of these processes by demonstrating that they have essential social components. Starting with the fact of the cumulative nature of science, sociologists have pointed out that the established body of scientific ideas and methodologies at any given time itself has the most important influence on setting problems for scientists to solve and on providing leads for their solution. This determining effect of the established ideas and methods is the source of the innumerable examples of the pattern of independent multiple discovery in science. Given the prerequisites of a discovery in the established body

of science, it is almost inevitable, as Ogburn (1922) and Merton (1961) have argued and demonstrated from the history of science, that independent multiples will occur. Some discoveries, of course, break somewhat more sharply than others with the fundamental notions of the established science; they have more emergent novelty. These are what Kuhn (1962) has called "scientific revolutions." However, even these are far from *ex nihilo*. Although cumulative in important measure, they also set new directions for the relevant fields and specialties in science.

Recent theory and research in the sociology of science have also qualified the older picture of the processes of scientific discovery as based entirely on foresight, planning, rationality, and ready acceptance. These characteristics certainly can be seen in large measure in most discoveries. But, in addition, in many discoveries there is an admixture of the unplanned, the nonrational or irrational, and the obstructive, contributed by the discoverer himself or by others. These characteristics manifest themselves in the pattern of serendipity in discovery and in the pattern of resistance by scientists themselves to certain scientific discoveries. The serendipity pattern occurs, and in actual research it occurs very often, when the researcher comes by happy chance on something he was not looking for, that is, some anomaly that presents him with the unexpected opportunity to change his preconceptions about his research and make a new discovery (Barber 1952, pp. 203-205). The resistance pattern occurs when the scientist refuses to accept his own or someone else's discovery because of theoretical or methodological preconceptions, the force of superior authority or prestige, or the prejudices of particular schools of thought (Barber & Hirsch 1962, chapter 32).

Of course, there has always been some resistance to scientific discoveries on the part of cultural and social institutions outside science. Religion, political and economic interests—indeed, the whole range of social factors that interact with science—have under some conditions opposed one or another scientific idea or requirement, just as they have also supported others. An important task for the sociology of science is to analyze specific sources of acceptance and resistance for specific types of scientific ideas and needs.

### Science as a social problem

Like the relations among any of the parts of society, the relations between science and various other parts of society are often inharmonious, as the participants in these relations see them, or

dysfunctional, as the objective observer sees them. Thus, sociology can also study science as what it calls, in general, "a social problem." There are two aspects of science as a social problem. In one aspect, science is an activity whose participants feel, in some important measure, angry or hostile to society because their values and needs are not being properly met or respected. For example, scientists resent what they define as unnecessary controls on their work: they complain about insufficient financial support for their preferred types of research; they deplore politically imposed secrecy; and they try to throw off all nationalistic and other parochial limitations on their research and communication activities. However much these frustrations may be necessary in the light of other social needs than those of science, to scientists they are social problems calling for protest and reform. A variety of organized and unorganized means of protest now exist among scientists to cope with these problems.

In another aspect, science is a social problem to various social groups who consider some of its consequences harmful to themselves and who therefore want to restrict or even eliminate science. Over both the short run and the long, many of the consequences of science are in fact harmful to various social groups. However unintended in most instances, these harmful consequences raise the issue of the social responsibilities of scientists, who are in part their source. It has come to be seen that responsibility for the harmful social consequences of science belongs not directly with scientists but with the several established social and political processes for handling social problems. It has also come to be seen that scientists can play a variety of useful roles in these social and political processes. If scientists have no absolute responsibility for the troubles they help to bring, neither are they absolved from all concern. A number of social and political arrangements are now being worked out to permit scientists to act as expert advisers on the technical aspects of the social problems they have helped to bring into being or that they can foresee arising out of their activities.

## IV

## SCIENCE-GOVERNMENT RELATIONS

The spectacular achievements of scientists during World War II not only made science obviously more important as an instrument of national policy but also gave it a role of greater independence and initiative in the economic and political systems of the world.

At least since the Enlightenment, it had generally been assumed that the advancement of science would contribute to social and political progress, but the specific role of science, and of scientists, in economic affairs had generally been thought of as subordinate to that of the entrepreneur or manager and, in matters of government policy, to that of the politician and bureaucrat. Especially in the English-speaking countries, the way of thinking initiated by Bacon, and re-emphasized by Franklin and Jefferson, assumed that scientific progress would be maintained by the patient accumulation of facts required for the solution of practical problems, and that research should therefore be supported as incidental to particular industrial enterprises or governmental programs or as a by-product of the system of higher education.

Among leading scientists, this assumption had come to seem less obviously true in the late nineteenth or early twentieth century, in view of the superior accomplishments in fundamental science of various countries in western Europe. The success of Napoleonic France in creating, under governmental auspices, strong institutions for the support of basic science as well as technology, and the state-encouraged systematic advancement, late in the nineteenth century, of research in the universities and industry of Germany, made British and American scientists begin to doubt that the inductive and applied approach in the laboratory and the complete independence of science from political issues and governmental support were still the best means of advancing science.

These doubts were confirmed by the institutional innovations of World War II, which, particularly in the United States, put science in a quite different relation to government. In its military application, it was no longer merely an instrument for the improvement of weapons at the request of military planners: it was a source of independent initiative in the invention of entirely new systems of weapons, to which war planners were forced to adapt

their strategies and diplomats their systems of international relations. Similarly, industrial research or development was no longer to be undertaken only at the initiative of the individual inventor or supported only on the basis of the calculation of the individual corporation; government planners began to look on it as a possible instrument by which government might foster the growth of the national economy and the solution of major social problems, and local communities became eager to foster it as an incentive to the development of their prosperity.

Even more important, political leaders no longer assumed that basic research would be adequately supported as a by-product of the system of industrial enterprise or private education; in the United States, where private universities were most jealous of their independence from political control, the federal government was called on to support, on an unprecedented scale, the basic research carried on in universities and in industrial laboratories. At the same time, scientists and scientific societies began to think of their role in society, not as one of detachment from governmental affairs and not as one of subordination to industrial managers and bureaucrats, but as one of responsibility for the nature of policies and of the institutional system in which science would be fostered and protected.

As a result, the relationship of science to government took on a new degree of significance and interest in the eyes of social scientists.

Since the fostering of science was to be a deliberate policy of government, the sociologists and psychologists were concerned with the identification of the types of personality and the nature of the educational and social environment that would develop creativity and encourage innovation (Research Conference . . . 1963; Roe 1953). In practical terms, they had to deal with the new systems of communication and computation, the management of laboratories, the relationship of scientists to administrators, and the status of professional and scientific groups in the social and political system (Hill 1964).

Since science was considered a potent force for economic growth, economists were led to study the criteria for the allocation of resources for the support of research and development (Nelson 1959). The relation of science and technology to the business cycle, the processes of innovation, and the relationship of business to government in the advancement of technology posed problems quite different from those of either classical or Marxian economics.

Students of politics and administration were

similarly required to consider how far the new techniques of operations research and other methods developed by scientists could go in determining political issues, and what effect they would have on the traditional values and on legal and political processes. These theoretical questions had their practical parallels within government: the relationship of scientific to administrative personnel within the civil service, the status of scientists as advisers to political executives or as participants in political action, and the extent to which representative legislative bodies should organize themselves to deal directly with scientists and with issues concerning the support and application of science (Gilpin & Wright 1964; McCamy 1960).

### Major areas of concern

Problems like those mentioned above had their greatest impact, of course, in the major nations, notably the United States, the United Kingdom, the nations of western Europe, and the Soviet Union, but during the 1950s they also began to be a concern of those interested in the economic and political development of other countries. Let us note three of the major fields in which these new problems arose and then consider their effect on scientific institutions, on governmental institutions, and on the nature of their relationship.

**Science and military strength.** The success of scientists in creating weapons that were not merely improvements on existing weapons systems but entirely beyond the imagination of military planners gave scientists quite a different status in government. Military strength could no longer be measured mainly in terms of mass armies and a system of industrial mobilization for the manufacture of munitions. It depended on the rate of scientific advance and the innovating ability of scientific institutions.

Accordingly, a substantial portion of the budgets of major countries came to be devoted to military research and development programs, and scientists and scientific institutions came to have a large share in the control of such programs.

As a result, the expenditures for research and development by government increased sharply, both in actual amounts and in proportion to other sources of support. In the United States, for example, total expenditure on research and development in 1940 (public and private) was well under \$1 billion, the government share of the total was certainly less than one-fifth, and the military services provided much less than the Department of Agriculture. In 1964 the federal government provided about \$15 billion, roughly two-thirds of

the national total, but spent four-fifths of its funds through private corporations and universities. About \$14 billion of the government total was contributed by the Department of Defense, the Atomic Energy Commission, and the National Aeronautics and Space Administration, the three agencies whose motive for expenditure was most clearly the strengthening of national power and international prestige (U.S. National Science Foundation, *Federal Funds* . . .).

The newest and most powerful weapons systems have been developed, not in the traditional military laboratories, but in technological institutions directed by civilians. In the United States during World War II, the Office of Scientific Research and Development, a civilian agency within the Executive Office of the President, set up an extensive network of contractual relations with universities and industrial corporations, and the Manhattan District of the Army Engineers, which finally developed the atomic bomb, followed the same general pattern (Hewlett & Anderson 1962). As a result, the postwar structure of weapons research and development was one involving heavy reliance on private institutions by the military services, the Atomic Energy Commission, and (later) the National Aeronautics and Space Administration. In the planning of these programs, considerable influence was exercised by advisory committees representing the private scientific institutions. Their influence was greater in the decisions relating to the support of basic research, but it carried considerable weight even in the development of weapons systems (Price 1954).

Scientists in wartime proved to be useful not merely in developing particular weapons but also in devising more effective systems and procedures of tactics and strategy. Operations research applied rigorous and quantitative methods to the solution of problems faced by the military commander, the industrial manager, or the political executive. Such work was organized either within the regular framework of the military services or under the sponsorship of independent research corporations. The flexibility of the contracting method in the United States was shown when the government proceeded to sponsor the creation of private corporations, supported by government funds, for the purpose of assisting governmental authorities in making major decisions on government administration or policy (U.S. Bureau of the Budget 1962). Of these new institutions the RAND Corporation, set up to serve the Air Force, was perhaps the best known, and the techniques that it developed, drawing on the skills of social as well as physical sci-

tists, became important tools for the civilian executives in the Defense Department who sought, in the 1960s, to exercise more effective control over military affairs. [See MILITARY POLICY.]

**Science and economic growth.** Soon after World War II, even those countries committed to the preservation of private economic enterprise had also committed themselves to a policy of maintaining a high degree of employment and fostering economic growth and prosperity. To these countries and others, it was obvious that some of the most dynamic economic growth was taking place in branches of industry which had been stimulated by the advance of technology for military purposes—notably, electronics, aircraft, plastics, and computers.

Economists accordingly took note of the extent to which scientific research and technological development, as well as capital investment, contributed to economic growth. Accordingly, one of the principal motives which led governments to support scientific research was the belief that research and technical education were major factors in the increase in productivity (Denison 1962). Even though economists may not agree on the precise percentage of economic growth which may be attributed to technological advance and the improvement in technological and managerial education, the belief in their efficacy has helped to persuade the United States and most nations of western Europe to increase their research and development expenditures in recent years at a much more rapid rate than their gross national product (Organization for Economic Cooperation and Development 1963, p. 22). In the United States the state governments and local business organizations have been persuaded that federal research subsidies have much to do with the location of new industries in their respective areas, and accordingly the expansion of universities and research laboratories has taken on an importance within the American political system much like that of the traditional forms of public works (such as the improvement of harbors or the building of dams).

At the same time, economists have become more skeptical about the extent to which research undertaken for military purposes will have useful by-products for the civilian economy. In western Europe, where various countries have undertaken to plan the development of the economy, including those sectors carried on by private industry, efforts have been made to develop scientific research as a means of economic growth (Parliamentary and Scientific Conference . . . 1965). The National Economic Development Council of Great Britain and

the Commissariat au Plan of France, for example, have set up special relationships with their respective national organizations for the planning of scientific research expenditures.

In the United States, on the other hand, it proved more difficult to build up federal government research and development programs specifically for the purpose of assisting in the development of private industry. The opposition of private business interests restrained the expansion of certain programs of scientific research and technological assistance in the Department of Commerce, for example, even while federal research support was being increased in other fields relating to the private economy, notably in agriculture and natural resources.

The apparent influence of science and technology in advancing economic growth led naturally to the hope that science could play an important role in the advancement of the underdeveloped countries. This hope found expression in the programs of the several specialized agencies of the United Nations, notably UNESCO, the Food and Agriculture Organization, and the World Health Organization. It became an important element also in the foreign aid and technical assistance programs of various individual nations—notably the United States, which was able to draw on its century of experience in agricultural education and research. [See ECONOMIC GROWTH.]

**The health sciences.** Some of the most striking practical accomplishments of the sciences have been in the fields of medicine and public health, and the medical profession and hospitals accordingly have been involved in the research programs supported by government to a rapidly increasing degree.

In the United States the National Institutes of Health (NIH) of the U.S. Public Health Service became during the 1950s the principal supporter of biological and medical sciences, not merely in the United States but throughout the world. American universities were receiving grants for basic research in even larger amounts from the NIH than from the military services or the National Aeronautics and Space Administration, and NIH grants throughout Europe had begun to add significantly to the research funds available to university scientists and to encourage the development of new patterns of research organization.

The official health programs supported by grants from the U.S. government and from the World Health Organization continued and extended the earlier international programs for the eradication of disease of such charitable organizations as the

Rockefeller Foundation and developed them further with the help of techniques developed or advanced by wartime research programs. The success of such efforts in reducing the death rate intensified concern with the problem of a population increasing at a rate which seemed to threaten the food supply and the economic progress of the various underdeveloped regions, especially the newly independent countries of Asia and Africa. [See PUBLIC HEALTH.]

### Institutions of basic science

Universities, which in their organization still retain traces of their medieval ecclesiastical origin, are in most countries the principal institutions for the conduct of basic research. In the major countries of continental Europe, they generally came under the patronage of the state, and their programs of scientific and technological research were seen as serving national purposes. Particularly in France and Germany, strong centers of fundamental research were thus developed with government support at a time when the ancient British universities were still dominated by classical studies and were generally uninterested in the advancement of science, and American institutions of higher learning were either denominational colleges or state institutions preoccupied with comparatively low levels of vocational and technical education (Ashby 1958; Cohen 1963).

The twentieth-century progress of science in the United Kingdom came in the basic sciences and mathematics at Cambridge (and later Oxford) and even more notably in some of the newer universities that even in the nineteenth century had been concerned with technological training and the needs of industry. A major share of the cost of these universities was taken over by the national treasury but was channeled through the University Grants Committee in such a way as to insulate the universities from political control.

In the United States, basic research before World War II was carried on mainly by the major universities, private or state, which received extensive assistance from the philanthropic foundations in the form of grants for special research projects. The leadership of the scientific societies and some of the philanthropic foundations had, by World War II, been persuaded that the nation should greatly increase its emphasis on fundamental research (U.S. National Science Foundation 1960). The patterns that had been developed by the grant-making programs of the private foundations were influential in determining the system of government support for such research in private and state

universities after 1945. That system supplied funds from several executive departments and agencies to universities and private corporations, under a system in which panels and committees of advisers from the private institutions were given great influence in the allocation of grants for specific projects. At the same time, the President's Science Advisory Committee, its members drawn mainly from private institutions, put great emphasis on a policy of keeping basic research and the teaching of graduate students closely connected within the universities, a policy that in addition to its pedagogical advantages had the merit of strengthening the autonomy of the academic and scientific community (U.S. President's Science Advisory Committee 1960).

The Soviet Union, on the other hand, chose to divide the functions of higher education from those of advanced research and generally to assign them to separate institutions. Research was directed through a system headed by the Committee on the Coordination of Research and Development, the Academy of Sciences, and corresponding academies for the several constituent republics (DeWitt 1961, pp. 434-435). In theory, the entire program is under the guidance of the principles of dialectical materialism; in practice, this guidance seems to affect the conduct of research least in the physical sciences, more in the biological sciences, and still more in the social sciences and humanities.

### Scientists in administration and politics

Basic as well as applied research is conducted not merely in universities but also in government laboratories set up to further the purposes of particular departments or ministries. The way in which their work, as well as the work of scientists in industry and universities, will be related to government policy and government programs depends to a great extent on the status, within the political system and the administrative service, of men trained in the sciences and related professions.

In the Soviet Union, the break with traditional systems of education and the great emphasis on scientific and technological training cleared the way for the advancement of scientists and engineers to positions in the higher ranks of the bureaucracy, and their advancement was further encouraged by the absence of separate cadres of private business managers and of institutions for their education. By contrast, the career administrative systems of western Europe and the United Kingdom have been comparatively resistant to the promotion of scientists and engineers to high administrative positions. In Germany, for example, a

legal education remains the normal basis for administrative advancement, and in Great Britain the highest class of the civil service is still dominated by permanent officials whose education was in history, the classics, and related fields of knowledge.

The personnel system of the United States, which lacks an elite corps and encourages exchanges between the civil service and private life at all levels in the hierarchy, has made it comparatively easy for scientists and men with technological education to rise to high administrative positions. The continuous interchange between governmental and private careers makes the government service a much less distinct part of society, and the distinction between governmental and private careers is further confused by the recent growth of the practice of contracting with private corporations and universities for the performance of government functions, especially research and development programs. As a result, the leading scientists, based in private institutions, who are called on to serve in a part-time or advisory capacity within the structure of government acquire an unprecedented degree of influence.

In the United States this advisory function takes the institutional form of a hierarchy of advisory committees, some of a continuing nature and some *ad hoc*, set up in the principal civilian agencies and military services, and in the White House itself. The most difficult administrative problems relating to the use of such committees have to do with their relationship to the main line of administrative authority, including the full-time staff. The first tendency after World War II was to look to the part-time advisers alone for the principal policy and administrative decisions, notably in the major advisory committee attached to the Executive Office of the President and the Office of the Secretary of Defense. But with the abolition of the Research and Development Board of the Department of Defense and the eventual substitution of a much more powerful individual officer, the director of defense research and engineering, and with the transformation of the President's Science Advisory Committee by the provision of a full-time chairman supported by a full-time staff, a more effective relationship was devised between the part-time adviser and the full-time official, and more sophisticated concepts were worked out with respect to the particular ways in which part-time advisers could most usefully be employed (Gilpin & Wright 1964).

The entire system is under the powerful influence, and often the detailed control, of congressional committees that have been making direct

use of independent scientific advisers, especially through the mechanism of the National Academy of Sciences. In countries with parliamentary forms of government the general response to a similar need was the creation of interministerial committees to deal with government-wide scientific problems, often drawing on the advice of committees including private scholars. Thus in the Federal Republic of Germany an interministerial committee exists side by side with an advisory council on science and the humanities and a committee on cultural policy and publicity of the parliament. Similarly, in France an interministerial committee reporting to the premier is advised by a consultative committee of scientists and economists, both committees being served by a single secretariat (the *Délégation Générale à la Recherche Scientifique et Technique*). The *Délégation Générale* works closely with the national planning agency (Parliamentary and Scientific Conference . . . 1965).

In the United Kingdom the Advisory Council on Scientific Policy was set up to advise the lord president of the council, who was responsible for the general program of civilian science in Great Britain. The lord president's responsibilities were later transferred to a newly created minister for science, whose functions were divided in 1964 by the newly elected Labour government between a minister for science and education and a minister for technology. Unlike the United States or the major countries of western Europe, the United Kingdom has no standing parliamentary committees dealing with particular scientific and technological programs, but it has the informal Parliamentary and Scientific Committee, including members of both houses of Parliament and representatives of more than one hundred scientific and technical organizations, to further the processes of consultation and the exchange of information between the worlds of politics and science.

The interest of national governments in science policy has been furthered by studies conducted by various international organizations. The Organization for Economic Cooperation and Development, the United Nations Educational, Scientific and Cultural Organization, and the North Atlantic Treaty Organization have all urged more comprehensive and consistent policies for the support and the coordination of scientific programs, and for more responsible forms of organization to deal with science at high policy levels.

Similar international discussions led to the formation of more effective international associations for the promotion of the several sciences, most

of them being grouped under the International Council of Scientific Unions with the support of UNESCO, and to the formation of international organizations for the conduct of scientific programs. Some of these latter organizations were set up for the operation of specific temporary programs, such as the International Geophysical Year, and others provided regional organizations for tasks too expensive or complex for single nations to undertake (for example, the European Organization for Nuclear Research, the European Atomic Energy Community, and the European Space Research Organization).

The conviction that scientists have a moral and political responsibility for the consequences of their research led many of them to abandon their old posture of political indifference or neutrality and to organize to take part in public affairs not merely as subordinate advisers but as active participants. This conviction led to the formation of many organizations for public education and the expression of policy opinions, their status and methods of operation depending greatly on the degree of freedom permitted to voluntary associations by the philosophy and traditions of the various countries. In the United Kingdom and western Europe, the leadership of such organizations tended before World War II toward a socialist or Marxist political philosophy. Since 1946 this tendency has been counterbalanced by theoretical arguments and organizing efforts in support of scientific freedom and against political control of research or economic enterprise. A good example is the program of the Congress for Cultural Freedom. In the United States, the political activity of scientists has been less influenced by ideology and less committed to particular political parties; it has concentrated more on specific policy issues and on the fostering of interest in public affairs within the scientific community (Price 1965).

## V

## SCIENTISTS

The word "scientist" was introduced into the English language around 1840 to distinguish those who seek empirical regularities in nature from philosophers, scholars, and intellectuals in a more general sense (Ross 1962). Mathematicians and logicians are usually regarded as scientists, although mathematics ceased being regarded as an empirical science by 1890–1910, and today the rubric also covers specialists in the social sciences almost without qualification. Other European languages have no terms strictly equivalent to "scientist." The French *savant*, Italian *scienziato*, German *Wissenschaftler*, and Russian *uchëny* also refer to philosophers, historians, and other systematic scholars. The absence of a verbal distinction is sometimes reflected in the organization of science and scholarship; for example, philosophers and historians are included in the Soviet Academy of Sciences.

Persons in a wide variety of statuses and roles are described as scientists or identify themselves as scientists in English-speaking societies today. In a narrow sense, a scientist is a man of scientific knowledge—one who adds to what is known in the sciences by writing articles or books. This is perhaps the only sense in which the word should be used without qualification. However, "scientists" also engage in applied research, attempting to make discoveries which will lead to new industrial, medical, and agricultural products or processes; in industrial development, applying scientific knowledge to specific problems of innovation in production; and in the routine testing and analyzing of commodities and processes. Such persons are called applied scientists and are not easily distinguished from engineers and technicians. Persons called scientists may also engage in teaching science in institutions of higher education, in writing accounts of science for laymen, and in administration. Finally, a scientist may be defined as a person

who has received a college degree in a scientific field.

**The population of scientists.** Estimates of the number of scientists vary according to the definition of the term and are, in any case, difficult to make. In the United States around 1962, there were more than one million persons with scientific or technical degrees, more than 275,000 members of professional scientific societies, more than 118,000 persons listed in *American Men of Science*, and roughly 100,000 engaged in basic or applied scientific research. The number of persons making substantial contributions to knowledge is, of course, much less than 100,000. The United States leads the world in the number of scientists. Between one-fourth and one-third of all scientists may be Americans, and most of the remainder are in the other industrialized nations. (For example, seven leading industrial nations accounted for more than 80 per cent of the articles abstracted in *Chemical Abstracts* in 1960. There is naturally an even greater concentration of scientific languages: English, German, Russian, and French accounted for more than 90 per cent of the more than ten thousand articles abstracted in *Index Chemicus* for 1963.) Many scientists move to the United States from other nations, industrialized as well as underdeveloped, to obtain better conditions for performing research; this concentration has caused concern among leaders in many nations.

The numbers cited above are changing rapidly. The growth in the number of scientists since the later Middle Ages has been exponential; thus, the scientists living in 1960 probably constituted more than 90 per cent of all those who ever lived (Price 1963). The rate of growth around 1960 would double the number of research scientists in roughly fifteen years. This rate of growth, however, must decline within the next generation in developed nations.

In the United States in 1952, about half of the science doctorates were received in the physical sciences and mathematics, about 22 per cent in the biological sciences, and about 28 per cent in the social sciences, including psychology. The relative proportions in these major subareas of science have not changed much in the last half century. Social scientists constitute a much larger proportion of scientists in the United States than they do in most other nations.

**Evolution of scientific roles.** The concept of the scientist developed only with the professionalization of science in the first half of the nineteenth century; previously, scientific activities were a subsidiary aspect of other social roles. Florian Zna-

niecki (1940) has written a concise sociological account of the historical differentiation of scientific roles. In most preindustrial societies, science has been the activity of practical actors. In ancient and medieval Europe, scientists were academic and often religious teachers. Beginning about the time of Galileo's move in 1611 from the University of Padua to the court of Cosimo de' Medici in Florence, scientists left the universities, and during the seventeenth and eighteenth centuries the amateur scientist flourished: either the gentleman scientist, like Robert Boyle, or the middle-class amateur, like Joseph Priestley. Scientists again became established in universities after the French Revolution. The twentieth century has seen the rapid growth of research establishments in business firms and government agencies. Of Americans receiving the doctorate in 1958, 56 per cent of the physical scientists, 31 per cent of the biological scientists, and 19 per cent of the social scientists took employment in industry or government. In the United States, most basic research is conducted in academic settings, but most of it is conducted in nonacademic research institutes in the Soviet Union and in some western European nations.

### Scientific careers

Roughly 90 per cent of American physical scientists, and slightly smaller proportions of biological and social scientists, are men. Like other professionals, they are recruited disproportionately from upper-middle-class families; but, unlike others, they are much less likely to be from Roman Catholic families and more likely to be from Protestant or Jewish families than would be expected by chance. During the interwar years, a small number of small liberal arts colleges contributed a disproportionately large share of those who went on to become scientists. Much of this resulted from selective recruitment into these colleges, but some probably resulted from their distinctive scholarly ethos. The growth of scientific education has been accompanied by a growth in the proportion of scientists produced by large public and private undergraduate institutions.

**Education.** Scientific education was revolutionized in nineteenth-century Germany by the dissertation: the requirement that the student conduct original research before receiving a degree. This innovation was soon copied in other nations. Today scientific education is prolonged and highly specialized, especially in its later stages. The dissertation research is usually conducted in a quasi-apprenticeship relation with a university professor, and students often make significant contributions to the research of their professors. Almost all

American graduate students in the sciences receive stipends for this work. The median number of years elapsed between the bachelor's degree and the doctorate for Americans receiving the doctorate in 1957 was six in the physical sciences, seven in the biological sciences, and eight in the social sciences (see Berelson 1960 on this and other aspects of graduate education).

Although many American universities give advanced training in the sciences (110 gave doctorates in chemistry in 1960), students tend to be concentrated in those institutions best known for basic research; the 15 universities with highest prestige accounted for almost half the doctorates in the sciences in 1957. The best graduate schools tend to recruit students from the best undergraduate schools, and their students are much more likely to be employed in leading universities than are graduates of institutions of lesser renown. Among those receiving advanced degrees, those who do best academically and identify most closely with their professors are most likely to go on to do research and teaching in universities; government and industrial laboratories tend to recruit those who do less well and are less committed to a research career.

**Career mobility.** There is now considerable mobility between universities and research establishments in government and industry; for example, more than one-third of American chemists have been employed in at least two of the three locales (Strauss & Rainwater 1962, chapter 6). The barriers to mobility of this sort were much greater before World War II and apparently are still great in most of the countries of western Europe. There is much less mobility between the major fields of science because of the specialized education required to enter any one of them.

Scientists in all types of establishments are likely to combine research with other activities; a large majority of scientists combine research with such other activities as teaching, administration, and technical consultation. Vertical mobility takes different forms in different locales. Advancement in universities does not usually involve a qualitative change in the nature of the work; it still involves teaching and research. In government, and especially in industry, vertical mobility often involves advancement to administrative positions and the abandonment of research; many firms recruit managers for line operations from among their research scientists (Kornhauser 1962, chapter 5).

### Incentives and occupational personality

Scientists in basic research are strongly motivated to solve intellectual problems that they re-

gard as intrinsically important, but the most important *social* incentive for them is their desire to obtain recognition from their colleagues for their research accomplishments. This desire leads the scientist to publish his results, and it influences his decisions in the selection of research problems and methods. Scientists compete strenuously to be the first to publish discoveries, and simultaneous discoveries by two or more scientists occur frequently. When there is some question about which scientist made a discovery first, a priority dispute may arise. The frequency of such disputes and the intense bitterness which often accompanies them are telling evidence of the value scientists place upon the esteem of their colleagues (Merton 1957; 1963); however, priority disputes have become less frequent in the twentieth century. Industrial and governmental research establishments which conduct applied or secret research make it more difficult for their scientific employees to be recognized, and such establishments must offer relatively high salaries to scientists in order to induce them to accept this deficiency.

**Values and personality.** Compared with non-scientists, scientists are more inclined to prize the recognition of their colleagues and their professional autonomy above the rewards of income, organizational power, and community prestige. They are nevertheless among the most prestigious occupational groups. "Scientists" were ranked third in prestige among 90 occupations—just behind U.S. Supreme Court justices and physicians—by a cross section of the U.S. population in 1963; some scientific specialties were, however, ranked a good deal lower. There is some evidence that these distinctive occupational values characterize scientists even as university undergraduates (Rosenberg 1957; Davis 1966).

Many of the distinctive personality characteristics of scientists also appear to be produced more by selection than by university or occupational socialization. Scientists tend to be highly intelligent; possessors of U.S. doctorates in the sciences have a mean IQ of over 130 (from a population with mean 100 and standard deviation 20), which is not much different from the mean IQ of similarly qualified persons in other fields or the mean IQ of medical and law school graduates (Price 1963, chapter 2). Although the evidence is sketchy and incomplete, and although there is much variation among scientists, it also appears that physical and biological scientists tend to be "intensely masculine," to avoid close interpersonal contacts, and to avoid and be disturbed by emotions of hostility and dependency. These characteristics may help generate the scientist's desire for recognition for

his accomplishments from his colleagues. Physical scientists tend to like music and dislike poetry and art. As might be expected, creative scientists are unusually hardworking, to the extent of appearing almost obsessed with their work (see Research Conference . . . 1963 for summaries of studies on the personality characteristics of scientists). Stereotypes of scientists held by high school and university students are in crude accord with these psychological findings (Mead & Métraux 1957–1958; Beardslee & O'Dowd 1961).

It has been argued that the values of the Puritans—rational mastery of one's environment, worldly activity for the glorification of God, and individualism—helped to motivate them to pursue science in seventeenth-century England, and have resulted, even today, in a higher valuation of science among Protestants than among Roman Catholics; this is a matter of dispute, however (Merton 1939; Feuer 1963). In any case, scientists today are among the least religious groups in the American population, with respect to both religious beliefs and religious practices. Those in the behavioral and biological sciences, where religion and science are most likely to come into conflict, are least likely to be religious. Scientists also tend to support parties of the left in national politics. With regard to both religion and politics, there is evidence that the more productive scientists are less conservative than the less productive.

**Scientific productivity.** It is generally difficult to account for variations in scientific productivity in terms of personality or background variables. There is great variation in productivity; the probability that a scientist will produce  $n$  or more papers (if he produces at least one) is roughly proportional to  $1/n$ , and 50 per cent of the papers are written by about 6 per cent of the scientists (Price 1963, table 2, p. 45). The best background predictors of scientific productivity are the times required to get the doctorate and college grades, but these account for little of the variation. Contrary to common belief, productivity does not decline with age until advanced ages, 60 or over, are reached.

Social contexts may have greater effects on productivity, but these effects are not readily distinguished from the selectivity of the contexts themselves. Graduates and faculty of leading universities are more productive than others. Scientists who have adequate facilities and research assistance are more productive than those who do not, and those who maintain continuity in their research topics are more productive than those who do not. However, the kinds of contacts with colleagues and the quality of specialization make a difference. Scientists who perform multiple func-

tions, combining research with teaching or administration, have been shown to be more productive than those who devote full time to research. Scientists who have frequent contacts with colleagues possessing different research interests are more productive than those with few contacts or contacts only with others of very similar interests. Social isolation especially is associated with low productivity for most scientists; this is a major handicap for scientists working in underdeveloped nations.

### The organization of science

Scientists engaged in basic research are necessarily given considerable autonomy. If they are not free to evaluate the truth or falsehood of theories or the adequacy of research findings, science ceases to exist; and scientists also are usually free to select research problems and techniques within broad limits. Such autonomy exists in many universities and in a few governmental and industrial establishments. University departments place some restrictions on this freedom; for example, some research in logic or statistics may be felt to be not "really" mathematics, and scientists in mathematics departments may be discouraged from performing it. This may produce organizational strains, and these strains are sometimes resolved by the differentiation of existing disciplines and departments. The number of recognizably different scientific disciplines probably trebled between 1900 and 1960, and the formation of new disciplines shows no signs of stopping.

The autonomy of basic scientists conflicts with a frequent need to engage in cooperative research. Traditionally this conflict has been resolved by forming temporary teams of freely collaborating scientists or teams of a professor and his students. More recently, in fields like nuclear physics, cooperative research has been formalized; permanent groups of professional scientists are formed in which authority is centralized and a formal division of labor is established. In most fields in universities, however, the traditional forms of teamwork are much more common than such formally organized groups.

**Industry and government.** The importance that scientists place upon purely scientific goals, their desire to be autonomous, and their sensitivity to the responses of their disciplinary colleagues produce strains when they are employed by industrial and governmental agencies to help achieve practical goals. For example, the desire to select their own research problems leads them to resist accepting directions from organization superiors. Also, scientists tend to prefer working in units with their

disciplinary colleagues to working in professionally heterogeneous groups that are organized on the basis of industrial functions; and the desire to inform others of their discoveries conflicts with requirements of industrial and military secrecy. The typical industrial incentives of salary and power are less important for scientists than for other categories of employees, and, if scientists accept these incentives as primary, their commitments to scientific values and their scientific competences may be eroded.

Various ways have evolved for accommodating industrial organization and the typical organization of the scientific community (Kornhauser 1962). Industrial scientists are selected from among those most willing to accept the importance of industrial goals, and occupational socialization furthers this acceptance. In addition, industrial research organizations are often differentiated into fundamental research units and units more directly involved in practical tasks, and scientists are assigned to different units on the basis of interests and skills. Research supervisors are recruited from among superior scientists and tend to use persuasion more than formal direction. "Parallel hierarchies" of advancement may be offered, so that some scientists are promoted to positions giving them greater autonomy in research, while others are promoted to administrative positions. Finally, the patent system and similar procedures make it possible for scientists to publish some research findings while safeguarding the proprietary interests of firms in discoveries. These types of accommodations make possible the incorporation of scientists into industry without the sterilization of science.

**Professional societies.** In addition to their work establishments, scientists as scientists are organized into a wide variety of societies and associations. Most of the vast number of such groups are devoted to a specialized subject matter, and their major activities involve the communication of discoveries through meetings and journals. The oldest societies and those with highest prestige, like the Royal Society of London and the U.S. National Academy of Sciences, are interdisciplinary, and membership in them is by election. Such groups engage in facilitating scientific communication, but they also play important roles in formulating the science policies of national governments. So also do large national groups that are open to almost all scientists, such as the American Association for the Advancement of Science, the British Association for the Advancement of Science, and the Deutscher Verband Technisch-Wissenschaftlicher Vereine.

While there has been a tendency for the scien-

tific "society" to give way to the professional "association," none of these types of organizations is directly involved with questions of wage rates and working conditions. At most, these groups forward the occupational interests of scientists by protecting job titles through state licensing and certification, by elevating educational standards, and by lobbying for increased governmental support. There are a few trade unions for "scientists," but engineers and technologists dominate them and they are relatively ineffective.

### What is a scientist?

The concept of the scientist was originally formulated primarily to distinguish specialists in the natural sciences from philosophers, historians, and other intellectuals; the distinction began to emerge as clear and significant only around 1800. Today the differences between philosophy and an empirical, generalizing, value-free science are clearly recognized. It is known that the pursuit of science requires the full-time efforts of its workers, and provisions for scientific employment are abundant. Perhaps we have succeeded only too well in distinguishing scientists from other intellectuals. Today our major difficulties involve distinguishing scientists from engineers and technicians. Even when a scientist is clearly a man of knowledge, his knowledge is apt to be highly specialized and communicable to few others, even within his own discipline. Are scientists intellectuals? Or are they a culture (or cultures) apart? C. P. Snow's 1959 book, *The Two Cultures and the Scientific Revolution*, stimulated extensive public discussions of this (the essays in Holton 1965 are a good sample of the result).

Perhaps university professors find it too easy to discover a cleavage between scientists and others. Taking a longer view, one might conclude that scientific knowledge and the scientific approach to the world have been dispersed very widely and deeply in the populations of industrialized nations. Most of us have been deeply influenced by scientists in what we believe and how we believe. The willingness of populations to tolerate and support scientists may be some testimonial to this influence.

## VI

## SCIENTIFIC COMMUNICATION

The term "scientific communication" refers to the exchange of information and ideas among scientists in their roles as scientists. Menzel (1958, p. 6) defines it as "the totality of publications, facilities, occasions, institutional arrangements, and customs which affect the direct or indirect transmission of scientific messages among scientists." It is distinguished from everyday communication about physical reality in that it has reference to a particular body of generalized, codified knowledge. Ideally, each and every communication contributes to the corpus of accepted knowledge identified as science. This is accomplished chiefly by extending the boundaries, by modifying previously held hypotheses, and by introducing additional precision, clarification, or verification of existing knowledge.

Although the preferred means and the practices associated with scientific communication have undergone change in the last few centuries, full and open communication of scientific results has always been a foundation stone of modern science. With the establishment of the academies in the seventeenth century, word-of-mouth exchange of information and informal meetings were very quickly supplemented by informal correspondence and exchange of letters concerning scientific work and, later, by a quasi-institutionalized arrangement embodied in the office of secretary or correspondent; finally, these were followed by formal journals containing the proceedings of meetings and other communications. The scientific enterprise of that era was small enough to permit reasonably adequate communication on the basis of the small number of journals and the occasional publication of books, supplemented by face-to-face interaction and correspondence by letter.

The so-called "communications explosion" in science is new primarily in the sense that it is now widely recognized as a problem. But as Price (1963) has pointed out, the amount of scientific publication has been growing exponentially, doubling every ten to fifteen years over the past three centuries. While there is no universal agreement, one of the more "conservative" estimates is that there are over thirty thousand scientific journals presently in existence and that there are more than a million papers published in them each year (Gottschalk & Desmond 1962; Bourne 1962). The sheer number of papers being produced annually has brought open recognition of a number of serious communication problems. Among the more important ones are the time lag between the completion of a paper

for publication and its appearance in a journal; the increasing difficulty of "keeping up with the literature", and the increasing difficulties in searching the literature and retrieving relevant information. For these as well as a number of other reasons centering on a growing awareness of the importance of science for national welfare, economic growth, and even survival, interest in the communications problems of science has mushroomed since the 1950s.

The communications explosion within science has given rise to concerted efforts to deal with the problem on many fronts, especially with the aid of new technological advances. Through the use of computers and a variety of other technical devices, efforts are being made to facilitate the storage and retrieval of information, and considerable progress is being made along these lines (see Stevens 1965). However, some questions have been raised about this approach in terms of the changing functions of scientific communication. While professional librarians, documentalists, editors, linguists, abstractors, mathematicians, and others now broadly characterized as information experts seek to improve the effectiveness of scientific communication largely by technical means, social scientists have begun to examine the social aspects of the scientific communications process.

### The study of scientific communication

Despite the growing interest in and support for studying the scientific communications system, there is still little systematic knowledge about it. A review of what is known must, therefore, be guided by a broad conceptual scheme rather than restricted to the specific questions now thought to be crucial for an understanding of the subject. The scheme has three major components: the *functions* of scientific communication, for scientists as well as for science generally; the various *channels* through which communications flow, the intervening variables or *situational factors* which influence the relationships between channels and functions.

**Functions of communication.** Menzel (1958) lists a number of functions performed by scientific communication: (1) providing answers to specific questions, (2) helping the scientist to stay abreast of new developments in his field, (3) helping him to acquire an understanding of a new field; (4) giving him a sense of the major trends in his field and of the relative importance of his own work; (5) verifying the reliability of information by additional testimony, (6) redirecting or broadening his span of interest and attention; and (7) obtaining critical response to his own work. He notes, too,

Merton's seminal discussion (1957) of the importance to scientists of professional recognition—a major reward for scientific achievement which is also carried by the communications system of science.

An understanding of these functions helps to pinpoint specific problems in the communications process and calls attention to the importance of the many different forms of communication behavior in which scientists engage. This is undoubtedly an important first step in going beyond the purely technical aspects of the storage and retrieval of scientific information, and studies concerned with these functions should lead not only to a better understanding of the communications process in science but also, it is hoped, may have practical utility in suggesting ways to improve the process.

One of the most important functions of communications for science as a whole is to provide a cumulative record of the "certified" knowledge which exists at any given point in time. Without such a record it is doubtful that science could continue to develop as a viable system. This record constitutes the point of reference for each scientist, providing him with the foundation from which he may make his own contributions toward extending what is known. This is not to imply that what is already in the record is immutable. Quite the contrary—the record is always subject to change in the light of new evidence, newly available techniques, and new discoveries. But whether a contribution is an extension of previously accepted knowledge or a new interpretation of what is already known, it is always and necessarily a matter of the record.

The current communications crisis raises questions about the nature of this record as well as about a number of widely held assumptions concerning the nature of the scientific communications process. For example, the fact that a paper has been published has usually implied that it has been reviewed by a jury of competent peers. However, there is at least the suspicion that the continued proliferation of journals has inevitably "watered down" the rigor of professional review. It is not even always possible to establish a simple correlation between the quality of any particular scientific paper and the reputation of the particular journal in which it appears. In any case, the quality of papers published is becoming an increasingly important problem. No matter how much retrieval procedures may be improved, the question of what is worth retrieving deserves much more attention.

Another major assumption has been that once a paper is published, not only is it accessible to the

scientific community, but also it will actually be read by the scientists concerned. However, the flood of publications has tended to undermine the accessibility of relevant papers, at least within the traditional communications practices. Not only may a single paper be buried in the flood of all papers published, but accessibility is also impeded by the growing trend toward increased specialization of journals, so that relevant papers may appear in sources not normally reviewed. Finally, the flood of publications has made it impossible for any one scientist to read more than a small fraction of what is potentially relevant. Some preliminary studies indicate that perhaps only about 25 scientists may actually read any particular paper which is published.

Further, an increase in the amount of information in the field tends to place greater strain on the integrative capacities of theory in that field, so that relationships among the contributions of different scientists become more difficult to determine. As a body of knowledge becomes "disorganized" in this way, the significance and even the validity of new contributions are more difficult to assess, and effective scientific communication may become a property only of small networks of scientists working on the same specific topics rather than of an entire discipline (Hagstrom 1965).

**Channels of communication.** The growing awareness of informal or relatively private channels of communication among scientists (U.S. President's . . . 1963; Schilling 1963–1964; Kaplan 1964) is but one aspect of the general problem of the different channels of communication and the different functions of each. The various channels of scientific communication are usually thought of as ranging from the most formal to the most informal, in terms of the degree to which the information flowing through them is codified and generally available to all scientists. It is perhaps more useful, however, to think of them as ranging from *structured* or planned channels which are known about in advance (such as journals, books, and even announced meetings) to *unstructured* channels through which information is accidentally acquired (such as finding useful information in the literature while searching for something else, or a casual conversation which yields unlooked-for information). A further complication must be introduced insofar as we are dealing with a highly fluid situation in which yesterday's unstructured channels become tomorrow's structured ones. The ease with which one can talk by telephone to a colleague three thousand miles away may make this a far more effective means of finding particular bits

of information than the ordinarily accepted techniques of searching the literature.

While precise knowledge of the proportion of information important to scientists acquired through various channels is still lacking, everything we know indicates that there is a much greater reliance on "accidental" and unstructured channels than has formerly been realized. Menzel (1958, p. 47) emphasizes that "it becomes imperative to consider the information network as a system. . . . What is little better than an accident from the point of view of an individual may well emerge as a predictable occurrence from a larger point of view."

While it is possible to try to match different channels with the different functions performed by scientific communication as discussed above, in practice such an exercise appears to be futile. Each of the functions listed can be, and apparently is, actually served by many different channels. Thus, it is entirely possible that the answer to a specific question can be found in an article in a published journal, in a preprint which arrived in the morning mail, during the course of a telephone conversation with a colleague about some other matter, or in a chance encounter in the corridors outside a scientific congress. A review article might be the best single source for providing a sense of the major trends in a field, but one might also get the same results, and often more quickly, from talking to a number of colleagues closely involved in the field. In the present circumstances, it seems safe to say that merely exploring one channel or source (especially a traditional one) is not necessarily the most effective way of treading through the maze of messages being communicated.

**Participation in structured channels.** The literature of science, primarily journals, constitutes the most important structured channel of communication within science; roughly two-thirds of the scientists studied by several investigators cited the journals as the most important single channel through which they learned of new developments in their fields of primary interest (Menzel 1958; 1960). To keep up with secondary fields, scientists typically turn first to recent textbooks and then to abstracts and review articles for guidance (Menzel 1958). The degree to which a body of knowledge is theoretically well-organized seems to influence the concentration of important information in specific channels; Menzel found chemists (a relatively well-organized field) reporting that two-thirds of the articles they read would be found in the three journals they listed as "most important," while zoologists (a relatively unorganized field) reported that only a quarter of their reading would

be found in three such journals. He found also that an average of 8.18 journals was needed to account for 75 per cent of the nominations of "three most important journals" by chemists, while the comparable figure for zoologists was 15.76 journals (1960).

Price (1963, table 2, p. 45) suggests that 6 per cent of the men in a field will produce half the published literature in that field and 2 per cent will produce about a quarter of it. Reasoning after Lotka (1926) that the number of scientists producing  $n$  papers is proportional to  $1/n^2$  (an inverse-square law of productivity), he calculates that the average scientist should produce about 3.5 papers during his working career. Meltzer (1956), however, found that U.S. physiologists had produced an average of four to five papers (including chapters in books and coauthored papers) within three years, and Schilling (1963-1964) seems to arrive at an even higher figure for the lifetime productivity of bioscientists.

Such figures are not directly related to the use of the literature; Price (1963) finds that the "half life" of a given article is about 15 years; that is, half of the articles cited by papers published in a given year will be less than 15 years old. Various other studies indicate that the half life in use is much shorter than this; more than half of the withdrawals from two technical libraries studied were less than five years old, and more than half of the "reading acts" by scientists in a U.S. government laboratory were devoted to materials less than two months old (Menzel 1960).

The amount of time a scientist devotes to the use of structured channels probably varies greatly with situational factors, although little is known about this at present. On the basis of some 25,000 random-time observations of 1,500 U.S. chemists, Halbert and Ackoff (1958) conclude that nearly 50 per cent of their subjects' time is spent in some form of communication and a third of it in specifically scientific communication. Roughly 10 per cent of the chemists' time is spent in general discussion, slightly less than this in receiving information orally, the same amount in reading unpublished materials, and about 5 per cent is spent in reading published materials. Estimates of the proportion of reading done for "specific uses" rather than for "general interest" vary from 20 to 80 per cent, and they are probably influenced heavily by the ways in which the data were gathered as well as by situational factors (Menzel 1960).

A number of studies report that the average amount of time per week spent in reading published materials is about five hours, but situational

factors are again highly important. Scientists in basic research seem to devote only half as much time to reading as do scientists in applied research; however, the former are much more concerned with archival literature, while the latter make greater use of unpublished literature (Menzel 1960). Törnudd (1958) suggests that physical isolation from channels of oral communication produces greater dependence among Danish and Finnish scientists upon published literature, and the rate at which a field is developing seems also to be important—the more rapid the advances, the greater the reliance upon relatively unstructured channels (Menzel 1958).

Schilling's study of bioscientists (1963–1964) found that age is unrelated to dependence on written, as compared with oral, channels; the bioscientists typically rate the latter as only half as important as the former. Moreover, women in the biological sciences seem slightly more dependent on the literature, probably because they have fewer opportunities to engage in unstructured communication: they visit other laboratories less often, hold fewer professional offices, and receive fewer preprints.

As the amount of published literature increases, scientists are turning to other structured channels as well as to unstructured channels. Orr (1964) notes a steady increase in the number of meetings and conferences held in the biomedical sciences each year since 1927, an increase in the attendance at such meetings, and a slight increase since 1947 in the percentage of research funds used for travel. Menzel's study of 76 scientists (1958) found that they attended an average of 2.5 meetings per year, and Garvey (see American Psychological Association . . . 1964) found that psychologists in an academic setting attended an average of three per year, while those in a government laboratory averaged about two. Yet Menzel notes that relatively few scientists admit obtaining significant information from the formal presentations at meetings and concludes that "the functions of scientific meetings are not those which ostensibly motivate the bulk of their programs, but other forms of communication—symposia, corridor meetings, the presence in one room of those interested in a single area . . ." (1960, vol. 1, p. 47).

**Unstructured communication.** Unstructured (sometimes called informal or unplanned) communication among scientists often provides specific information which a scientist knows he needs, but probably its major importance lies in providing him with useful information which he did not know existed. Scientists generally report between 65 and

90 per cent success in locating needed information in the literature (Menzel 1960; Törnudd 1958), but they obviously cannot estimate their success in obtaining information of which they are unaware.

Such unknown information varies from the specific (a new experimental technique) to the general (news that another individual is working on a particular problem), but it is almost always obtained, directly or indirectly, "by accident." Considering the usual delays in publication and the general difficulties involved in keeping abreast of the literature, it is presumptive evidence of the efficiency of unstructured channels that only about one scientist in five reports ever having received information "too late"—that is, information which would have influenced the course of his research had he received it sooner (Menzel 1960).

Menzel notes four major unstructured channels through which information reaches scientists: a scientist informs a colleague of his current interests and is given an item of pertinent information in return; a colleague conveys information which he knows the scientist will be interested in; a colleague volunteers the information while they are together for a different purpose; and he finds a useful item of information in the literature while searching for something else. In all but the last, the scientist is dependent on his colleagues, who will know of his needs and interests only if he tells them or if they are indicated by his previous publications. The effectiveness with which a scientist uses these channels, then, would seem to be related both to his ability to make his needs known and to the frequency with which he comes into contact with other scientists in his field.

**The flow of professional recognition.** Unstructured channels can operate effectively only so long as scientists feel the need to assist each other and share the values of "communism" and "disinterestedness" which encourage them to share their findings freely, without regard for personal gain (Merton [1949] 1957, pp. 556–560). Yet personal gain of an honorific nature is involved; Merton has referred to this as professional recognition (1957), and Storer (1966) has suggested that it is "competent response" to a contribution. If information flows in one direction through the various channels of scientific communication, response to it flows in the other. Anything which signifies the value, to one or more scientists, of information received from others—eponymy, prizes, election to professional office, footnotes, even personal thanks—serves to sustain the scientist's motivation through confirming the goodness of his work and his successful performance as a scientist. Glaser (1964) has docu-

mented some of the consequences for the motivation and career plans of scientists when there is a lack of "adequate recognition," but work on the various channels through which recognition flows has barely begun (Kaplan 1965a).

### Improving scientific communication

The extent and success of efforts to speed and to make more effective the dissemination of information in science vary greatly by fields. In physics, the weekly *Physical Review Letters* has made it possible to bring brief announcements of recent findings to readers, usually within a month of submission, and there is a variety of other newsletters, data-card services, and regular announcements of work in progress which are now being established in different fields. The American Psychological Association's Project on Scientific Information Exchange in Psychology represents a major effort to develop and then apply new information to the improvement of communication within the field of psychology.

Another technique, facilitated by the use of high-speed computers, is the citation index, which enables one to trace the influence of a given paper forward in time; this will apparently be of value to historians and sociologists of science as well as to those concerned with the substantive content of the materials cited (Institute for Scientific Information 1964). The suggestion that archival publication be partially replaced by central depositories, from which materials may be acquired on request after learning of them through title lists and abstracts, has not yet met with success; the obstacles to its adoption apparently lie more in the desire of scientists to be assured that their contributions will go to a "guaranteed" audience (as when published in a journal) than in the technical problems involved (U.S. President's . . . 1963).

Suggestions have also been made toward providing greater opportunity for scientists to make use of unstructured channels of communication: encouraging attendance at meetings and visits to other institutions, arranging teaching duties so as to leave some days free for travel, and allowing more time at announced meetings for discussion sessions (Menzel 1958). Such suggestions are basically concerned with increasing the amount of personal contact among scientists, and their success will probably be contingent upon the amount of funds available for such purposes.

It may be predicted that the study of scientific communication will become increasingly important as the difficulty of disseminating information widely and rapidly mounts. The field requires much

more work in conceptualizing the nature of the communications network and its relation to the social structure of science, as well as in the collection of more data. While much of the concern expressed today about problems of scientific communication focuses on developing new techniques for the storage and retrieval of information, and while some concern is focused on the social aspects of the communications process, very little attention has been devoted to the underlying problem of what should be communicated and in what form.

Finally, there is little doubt that each scientist will have to bear a greater responsibility for the transfer of information and not leave it largely to the professional documentalist. As a recent analysis of the problems of scientific communication (U.S. President's . . . 1963, p. 1) notes, "The technical community generally must devote a larger share than heretofore of its time and resources to the discriminating management of the ever increasing technical record. Doing less will lead to fragmented and ineffective science and technology."

## SCIENTIFIC EXPLANATION

There is little disagreement that explanation is a major aim of science; there is much about the conditions that a proposed explanation must satisfy. Most of this disagreement, especially in history and in the social sciences, concerns the so-called nomological and deductive models of satisfactory explanation. There is also a more general controversy: many—perhaps most—scientists and philosophers maintain that these models clearly apply to the natural sciences and should apply to the social sciences as well, while others insist that they do not apply to any science, natural or social. For the most part, however, I shall bypass this controversy and discuss the applicability of the two models to the social sciences.

But first let us raise the logically prior question "What is an explanation?" There are three traditional answers to this: (1) to explain is to remove perplexity; (2) to explain is to change the unknown to the known; (3) to explain an event or type of event is to give its causes.

The first two answers have the virtue of reminding us of the psychological conditions that frequently obtain when we request an explanation. But this virtue is, in a way, the defect of these two approaches: they are too psychological, in the sense that they do not stipulate the logical conditions that must obtain before we have a satisfactory explanation. Clearly, not every way of removing perplexity can count as an explanation. Again, it should be noted that both of these approaches fail to point out that when we explain an event or type of event, we attempt to relate it to others like it and to give a systematic account of phenomena which will show how they are interrelated. In short, these answers fail to emphasize the systematic interconnection between explanation and theory construction.

The third answer does not share in these defects. The thesis that to explain an event is to give its cause is one that goes back to Aristotle and has been defended at length by Mill (1843) and other distinguished logicians. But this approach, whatever its virtues, cannot count as an adequate theory of explanation. At best it is a partial account of the explanation of events, but not of regularities, dispositions, and other types of phenomena

which we try to explain. Moreover, since the term "cause" is not in itself a very clear one, a theory which builds on it without attempting any explanation of it is not a reliable guide. However, many philosophers and social scientists have been convinced by the arguments offered by Hume and his followers that a causal statement entails a lawlike one, i.e., that a statement of the form "Event A caused event B" entails a statement of the form "Events like A regularly precede and are contiguous with events like B." If this analysis be granted, then the approach to explanation which emphasizes causation is compatible with the deductive and nomological models.

**Nomological and deductive models.** Supporters of the nomological model of scientific explanation insist that no event or regularity is explained by a proposed explanation unless it contains a scientific law (*nomos* is Greek for law). Supporters of the deductive model accept this but go further; they maintain that an event or regularity is explained if a sentence describing that event or regularity is deduced from a set of premises containing (a) a scientific law and (b) any other premises that may be required to make the deduction logically correct (provided, of course, that these premises are true).

Thus, given a sentence *P* that can be used to describe an event, the nomological model states that the event is not explained by a series of sentences  $S_1, S_2, \dots, S_n$  unless this series contains a scientific law. To this the deductive model adds that if  $S_1, S_2, \dots, S_n$  contains one or more laws, and if *P* can be deduced from  $S_1, S_2, \dots, S_n$ , then  $S_1, S_2, \dots, S_n$  is a satisfactory conjunction of explaining sentences. This assumes that *P* stands for a sentence describing a particular event. When we want to explain not an event, but a trend or a regularity, all the sentences needed, both descriptive and explanatory, would of course be far more complex, but the over-all form of the explanation would stay the same.

On occasion some defenders of the deductive or the nomological models add that the explaining premises  $S_1, S_2, \dots, S_n$  must contain or constitute a theory. But this addition does not clarify matters at all, because the meaning of the term "theory" is itself unclear. Sometimes the term is applied to any systematically interconnected set of sentences; sometimes it appears to mean the same as "hypothesis"; sometimes it is used interchangeably with "law." Clearly, if "theory" and "law" are to be used interchangeably, acceptance of either the deductive or the nomological model requires us to believe that when we explain, we appeal to or use a theory. Since the term "theory" has so many

uses, it is perhaps best to avoid using it in this context and to say simply that the premises of nomological and deductive explanations contain laws.

Candor demands, however, the admission that we are far from a completely satisfactory statement of either model. Thus, in the nomological model the meaning of "law" is just as much in dispute as that of "theory," while in the deductive model the kinds of sentences that may appear in the series  $S_1, S_2, \dots, S_n$  need to be specified in greater detail. On the other hand, there is little point in being concerned with such details if this whole approach to explanation is not valid. To see whether it is, I shall try to remove some misunderstandings about the nature of the nomological and deductive models, and in so doing to counter some of the arguments against them and admit the truth of others, at least in qualified form.

Do the models involve determinism? Both the deductive and the nomological models have been criticized on the grounds that they involve commitment to determinism. But this criticism is irrelevant. One may accept either model and still be agnostic about the thesis that every event is covered by laws—a thesis frequently given as one specification of determinism. Thus, philosophers who accept this thesis frequently argue that any sentence truly descriptive of an event is in principle deducible from some series of sentences containing one or more laws. But clearly this is not the same as claiming with the supporters of the nomological and deductive models, that if a sentence truly descriptive of an event is deduced from a series of sentences containing a law, then the event is explained.

Of course, many defenders of the nomological and deductive models do accept an even stronger version of determinism than the thesis that every event is covered by laws. But they often accept it as a "guiding principle of inquiry," to use C. S. Peirce's phrase. Thus, they may insist that the scientist should not merely seek a variety of general laws for explaining various events and regularities but should construct and confirm one general theory that would explain all events and regularities, or at least all those within the purview of a particular science. But obviously a guiding principle is not the same thing as an article of faith, and many supporters of the nomological and deductive models agree that there may very well be no such general theory or theories for scientists to discover.

Can social scientists use the models? The deductive and nomological models are sometimes

criticized on the grounds that social scientists have not succeeded in confirming any laws and therefore cannot use either model. To this it can be objected that some social scientists at least claim to have discovered laws, and that in any case only true or completely acceptable explanations, of which social scientists admit to having provided very few, are supposed to conform to the models' requirements.

But though the criticism as it stands is irrelevant, it does indicate that it is not enough to consider only true explanations or fully acceptable ones; we must consider not only the truth of proposed explanations but also their degrees of acceptability. Clearly, when a scientist proposes an explanation and employs a generalization, he obviously does not know that the generalization is true and, hence, that he is in possession of a law. The nomological and deductive models must therefore be supplemented, as follows. Let us use the term "lawful statement" to denote any highly confirmed lawlike statement—that is, any statement that (a) would be a law if it were true and (b) has in fact been found to hold true on numerous occasions. Explanations containing such statements have, other things being equal, a high degree of acceptability, and many of them also turn out to be true explanations—that is, the lawful sentences that they contain are true. But, of course, explanations that at one time were highly acceptable because the lawlike sentences they contained were at that time highly confirmed may turn out to be false (a classic case of this is Newtonian mechanics). This distinction between explanations that are acceptable at a given time and true explanations that simply conform to the deductive model is not *ad hoc*. Rather, it corresponds to the distinction, usually applied to statements, between "true" and "well confirmed."

Here it may be objected that social scientists do not refer to laws and, hence, that it is misleading to appeal to laws when discussing the logic of social scientific explanation. But this objection is a weak one. Social scientists tacitly employ many laws that are so well known that no special reference to them is needed. Furthermore, it should be emphasized that many social scientists do in point of fact refer to laws—economists, for instance, to Say's law of markets, and sociologists to Michels' "iron law of oligarchy." It may also be objected that the distinction between a highly confirmed generalization and a lawlike one is artificial. But once again the answer is readily available. Thus, in everyday life we would not treat the generalization "All American presidents are Christian" as lawlike

or as a candidate for a law, even though all the evidence to date for it is positive and, in that sense, it is well confirmed. Observe further that the distinction we are discussing here is parallel to, although admittedly identifiable with, the frequently made distinction between causal statements, on the one hand, and statements of mere association, or statements of correlations which may be spurious, on the other.

What, then, are we to make of proposed explanations that do not contain lawful statements? We certainly do not always know on what law, if any, an investigator has based his explanation of certain data, even if we are inclined to accept what he says. As an argument against the nomological and deductive models this is not a very strong one, since most social scientists would admit that such proposed explanations should be replaced by more carefully stated ones. Besides, if the acceptability of such an explanation depends, as it usually does, on the degree to which it approximates a nomological or a deductive explanation, then it cannot be called an alternative to these latter, but merely an inferior substitute for them.

**Motivational explanations.** It is a commonplace that social scientists offer motivational explanations, but it is not at all obvious how such explanations should be interpreted from a logical point of view. Note first that when a motivational explanation is offered, there is no necessary commitment to the thesis that there are private internal entities called motives which are responsible for behavior or action; all that is involved is some reference to the wants, preferences, or aims of the individual or group whose action is being described or explained. In this sense all Freudian theory, for instance, makes tacit or explicit reference to motives, and so do all explanations by economists that refer to the utility of the agent or group whose behavior is being discussed. Similarly, tacit reference is made to the aims of a person when sociologists or social psychologists appeal, in order to make sense of his behavior, to the reference group with which he identifies himself. What then are we attributing to a person when we attribute a motive to him? The answer can readily be suggested: we are attributing to him a disposition to behave in a certain way or a disposition to prize certain outcomes over others. But this constitutes another possible objection to the nomological and deductive models. When a motivational explanation is offered, no appeal is made to a general law about the way human beings behave but, rather, to a dispositional statement about an individual. But it is very difficult to give the exact grounds upon which we can distinguish

between laws and dispositional statements. Admittedly, it seems possible to do without general laws if we restrict our attention to those cases in which the action seems to have been inspired by only one motive and in which there is no need, for explanatory purposes, to consider what the agent thought about the alternative ways available to him for the satisfaction of his motive. But when we consider the more usual cases of action—action performed out of many motives and action after deliberation about alternatives—it will not do to consider only the agent's disposition. Can we handle both these latter cases by reference to law? The answer is not clear. Some social scientists have thought it plausible to assume, as at least a first approximation, that insofar as people are rational, they try to maximize expected utility. But many suspect that the generalization tacitly appealed to here is a disguised tautology. Nevertheless, the defense of this generalization, or of alternatives to it, indicates that in order to explain actions for which there are many motives, some social scientists do look for laws and, hence, act in accord with the deductive model.

Others suggest that we should not seek general laws but construct ideal types instead [see *TYPOLOGIES*]. To construct an ideal type explanation for an action *A* by a person *P* is (1) to impute at least one motive, *T*, to *P*; (2) to list the alternatives confronted by *P*; (3) to show that an action of the same type as *A* is a rational one—perhaps the only rational one—for *P* to perform, given *T*; (4) to show that performing *A*, given alternatives  $A_1, A_2, \dots, A_n$ , is an efficient way of satisfying *T*. If, given the same motive and set of alternatives, *P* does not perform *A*, defenders of the ideal type approach would suggest that we must institute a search for the factors making for irrationality on the part of *P*.

One argument against this version of the ideal type model of explanation is that the motive imputed to the agent may in fact be the wrong one; another is that the model is incomplete unless the terms "rational" and "efficient" are explicated. Moreover, ideal type explanation sometimes appears to depend on a general law about the behavior of rational agents and, hence, to approximate either the deductive model or, at least, the nomological one.

**Functional explanations.** Conclusions similar to those drawn above can, I think, be applied to so-called functional explanations, for these either lack *prima-facie* acceptability or, when they have it, are not evidently at variance with the deductive or nomological models. Thus, a common type of functional "explanation" may state merely that a certain institution plays an indispensable role in

a society. Such a statement provides us with nothing more than a necessary condition and, hence, lacks *prima-facie* acceptability as an explanation. However, the stronger types of functional explanation do show that, holding certain things constant, the presence of a certain mechanism is a sufficient condition for the existence of a certain state of affairs. In my opinion, explanations of this type conform to the deductive model, for to say that *S* is a sufficient explanatory condition for *T* is, I think, equivalent to saying that the statement "If *S*, then *T*" is not only true but also lawful.

Of course, we need more complex laws than the ones thus far discussed if we are to provide descriptions and explanations of events in systems that are purposive and self-corrective. But it is far from obvious that this requires a special kind of explanation called teleological, or functional, explanation, and even less obvious that societies—at least complex ones—can be analyzed in teleological terms. Certainly, societies are not totally purposive, nor do such purposes as they may sometimes be said to have (making war, for example) always remain the same. At most, societies may tend to reorganize themselves in order to keep certain properties constant. But it is hard to say which properties these are [see *SYSTEMS ANALYSIS, especially the article on SOCIAL SYSTEMS*].

**Causal explanation.** It has been maintained at least since Aristotle that to explain an event is to give its causes. But this does not necessarily involve controverting the nomological or the deductive models, since it can be argued that to give the causes for an event is to present a deductive explanation containing a causal law. Given this approach, we may then try to explicate the uses of the term "causal law."

A statement is occasionally called a causal law if it specifies either a sufficient condition or necessary and sufficient conditions for a certain type of occurrence. In logic, such a statement may take any of these forms: (1) if *A* then *B*; (2) *A* if and only if *B*; (3) *A* is a function of *B* (when *A* and *B* stand in the place of terms designating measurable properties). Deterministic laws, which describe how a system, with states that are described mathematically, evolves over time, are also called causal laws. Finally, the term "causal" is applied to laws of the form "if *A* then *B*" when (1) *A* denotes a type of event that comes just before an event of type *B*; (2) *A* and *B* are events or episodes in bodies or agents that are spatially contiguous; (3) the occurrence of *A* is to be considered a sufficient condition for the occurrence of *B* even though an event of type *B* might occur without one of type *A*.

preceding it. Stimulus-response generalizations frequently meet these three criteria—criteria that represent perhaps the most legitimate use of the term “causal law.”

Not all explanations that appeal, whether overtly or tacitly, to the notion of cause make use of causal laws in any of the senses discussed above. Accordingly, it is not evident that all causal explanations should conform to the nomological model, and still less to the deductive. Nevertheless, the view I am advocating has good philosophical precedent. At least since Hume many philosophers have argued that to assert of an event, *A*, that it caused another event, *B*, is equivalent to appealing tacitly to a law of the form “Events of type *A* are sufficient conditions of events of type *B* and precede them.”

This view is not completely persuasive. Often we say that an event *A* caused an event *B* when we mean only that the event *A* was a necessary condition for the event *B*. Also, we sometimes refer to an event *A* as the cause or a cause of an event *B* when we mean to assert that *A* was either a sufficient or a necessary condition for the occurrence of *B* only when conjoined with other such conditions. Moreover, when we say that *A* caused *B*, we are often unprepared to specify a general law relating events of type *A* to events of type *B*. Thus, we might be convinced that a given remark had caused the hearer to blush, but we might not be ready at the same time to cite a general law about the relation between remarks and blushing. Nevertheless, it does seem that when we specify a cause for an event and believe that this specification provides us with an explanation of the event, we tacitly commit ourselves to some generalization, however vague. Thus, to revert to the illustration given above, a person who insists that *X* blushed because *Y* said something might be challenged by *Z* to the effect that *X* didn't blush the last time he heard a similar remark, and that therefore the present remark couldn't have been responsible for his blushes. But this observation, though it helps to diminish the distance between explanations that contain causal laws and explanations that merely appeal to the notion of cause, does not abolish that distance completely. Whether it can ever be abolished is still under debate.

**Statistical explanation.** The status of statistical explanation, and its relation to nomological and deductive explanation, are topics subject to much philosophical controversy.

Statistical explanations are explanations containing lawlike statements based on observation of statistical regularities and/or on the statistical theory of probability. It is generally accepted that probabilistic statements, as interpreted in the sci-

ences, cannot be finally confirmed or even disconfirmed by observational evidence. It is also accepted that we cannot deduce from any statistical generalization a statement to the effect that any particular event must occur. [See PROBABILITY.]

It is not so widely recognized, however, that the problem of statistical explanation is much harder to deal with in the case of statistical generalizations that are either spatially or temporally restricted. Thus, if we knew that 90 per cent of the people in Milwaukee are Democrats and that 85 per cent of all living graduates of Yale University are Republicans, we could not use these generalizations as they stand to explain the voting habits of Yale graduates living in Milwaukee. It is therefore most important, when discussing statistical explanations, to appeal to the nomological, and not the deductive, model, for clearly we cannot expect to construct deductive explanations on every occasion when we use statistical generalizations for explanatory purposes. However, it would be a mistake to think that we can never have a deductive explanation under these circumstances, for we may deduce a statistical generalization from a conjunction of two or more other statistical generalizations.

It is important to note that we have not discussed the very complex but relatively typical situation that arises when social scientists who are using statistical data in an attempt to distinguish between the effects of several factors note that one factor is more relevant than the others for the purpose of explaining the phenomenon. Discussion of this and other such situations has been omitted because their logic is under much dispute. Many of the issues involved have been considered by Nagel (1952), though for some of the problems that are raised by statistical data and their analysis, the interested reader should consult works by Blacklock (1964) and Boudon (1965; see also Ando et al. 1963).

**Amplifying the models.** We have discussed some objections to the nomological and deductive models; it is now time to consider amplifying them in order to meet these objections. Let us begin by emphasizing the trivial point that we never explain an event as such, but only selected aspects of it. In other words, it is not the event itself that is explained but the event under a given description. Thus, if a person sits down on a tack and yells, we may say that he yelled because he sat on the tack. But we obviously are not ready to claim that we can explain the specific pitch or duration of the yell in the same terms.

Observe, however, that an explanation may be totally satisfactory once we specify what aspect of the event we are trying to explain. This is of special

relevance to the discussion of historical explanation. Historians have often noted that any event can be described in many ways and that some explanations of events are satisfactory only if the events are described schematically. Thus, we might be able to explain that a group migrated because it hoped to improve its lot but not be able to explain why it migrated on a specific date and to a specific country. Some historians, noting that there seems to be no end to the detail in which a given event can be described, have concluded that, for this reason, no event can ever be explained, nor can the causes of an event be fully specified. Against this view, I would like to urge that we discuss not the explanation of an event but the explanation of an event under a given description. This would allow us to accept some explanations as totally satisfactory even if we wanted to replace them with explanations of the same event under a more refined description.

Finally, it should be noted that in order to give an explanation of an event of a certain type, it is not necessary to cite laws or theories about events of that type. This is often overlooked in discussion of how to explain certain social phenomena; for instance, many social scientists seem to believe that in order to explain instances of crime or divorce, they need a general theory of crime or divorce. But this is dubious. To explain why a man slipped on a banana peel, we do not need a general theory of slipping. Rather, the laws that we need to cite are general laws in which terms like "slipping" do not occur. The essential point is that in order to explain an event, we often must redescribe it in terms of a given theory; moreover, two events that in ordinary life are both classified under the same general term may, for purposes of explanation, have to be described differently and explained by different general theories. To take an everyday example: A man who hurries to meet a friend and a man who flees to avoid disaster may both be running, yet the explanations for their behavior are different. More complicated examples, requiring explanations based on abstract theories, would require that the events needing explanation be redescribed in terms drawn from those theories. Although this type of redescription was not required in our example, the point remains that two events ordinarily classified as instances of the same type may have different explanations. The same applies to explanations involving not events but groups, epochs, social systems, and societies; we must specify what aspects of these entities we want to have explained.

## SCREENING AND SELECTION

Screening and selection procedures are statistical methods for assigning individuals to two or more categories on the basis of certain tests or measurements that can be made upon them. Of concern usually is some desired trait or characteristic of the individuals that cannot be measured directly. All that can be done is to obtain an estimate for each individual from the results of the available tests

and then to make the assignment on the basis of these estimates. The central statistical problem is to evaluate the properties of alternative schemes for utilizing the available data to make the assignments in order to choose the scheme that best achieves whatever objectives are considered to be most relevant for the particular application.

For example, some educational selection schemes may be regarded in this light. The individuals might be high school students and the categories "admit to college" and "do not admit to college." The desired trait is future success in college, but only tests at the high school level are available. (As will be seen, many examples of selection and screening are somewhat more complex than this, particularly in their use of more than one level of screening. In this educational context one might instead use three categories: "admit," "put on waiting list," and "do not admit.")

Denote by  $N$  the number of individuals to be assigned and let  $c$  be the number of categories. For any individual, let  $Y$  denote the unknown value of the desired trait and let  $X_1, \dots, X_p$  denote the measurements or scores that can be obtained and used as predictors of  $Y$ . The screening or selection procedure is a scheme that specifies in terms of  $X_1, \dots, X_p$  how each individual is to be assigned to one of the  $c$  categories.

The screening may be done at one stage—that is, all the measurements  $X_1, \dots, X_p$  become available before an individual is assigned—or it may be multistage. The advantage of a multistage procedure is that it may allow some individuals to be assigned at an early stage or, at least, to be eliminated from contention for the categories of interest, thus permitting the resources available for performing the tests to be concentrated on fewer individuals in the later stages.

The terms *screening* and *selection* are largely synonymous, although in particular applications one or the other may be preferred. Sometimes, in order to avoid the possible connotation that certain categories may be more desirable than others, a neutral term such as *allocation* is used. The term *classification* has a different shade of meaning, referring to the identification of which of several distinct distributions each individual belongs to (In taxonomy, for example, classification involves the assignment of an organism to its proper species) [see MULTIVARIATE ANALYSIS, article on CLASSIFICATION AND DISCRIMINATION].

Various formulations of screening and selection problems have been proposed and investigated. A bibliography containing more than five hundred references has been given by Federer (1963). Of

special interest is the case  $c = 2$ , in which the individuals are separated into two categories, a selected group and the remainder; the success of the screening procedure is judged by the values of  $Y$  for the individuals in the selected group. This article will be primarily devoted to this case of two categories.

### The case where $N$ is large

This section deals with the case of separation into two categories where either the number,  $N$ , of individuals is large enough for their  $Y$ -values to be considered as forming a continuous distribution or, alternatively, the  $N$  individuals themselves are considered as a random selection from a conceptually infinite population. The object of the screening procedure is to produce a distribution of  $Y$ -values in the selected group that is, in an appropriate sense, an improvement on the original distribution. For example, one might want the selected group to have as high a median  $Y$  as possible.

In many applications, the feature of the distribution of  $Y$  that is considered most important is its mean. For example, in a plant-breeding program,  $Y$  might stand for the crop yield of the individual varieties, and the purpose of the program might be to select a set of varieties whose mean  $Y$  is as high as possible. The difference in the mean  $Y$  for the selected varieties from that of the original group is referred to as the "advance" or the "gain due to selection."

Cochran (1951) summarized the mathematical basis for selection procedures designed to maximize the mean  $Y$  in the selected set. He showed that the optimum selection rule to use at each stage should be based on the regression of  $Y$  on the  $X$ 's that are known at that stage. In the case where the joint distribution of these variates is multivariate normal, this regression is the linear combination of the  $X$ 's that has maximum correlation with  $Y$ . [See MULTIVARIATE ANALYSIS, articles on CORRELATION.]

**Plant selection.** In a plant-breeding program for improving the yield of a particular crop, a large number of potential new varieties become available in any year. These are tested in successive plantings, and the better-yielding types in each planting are selected to produce the seed for the next sowing, until finally a small fraction of the original number remain as possible replacements for the standard varieties in commercial use.

Finney (1966) and Curnow (1961) have carried out an extensive theoretical and numerical investigation of a fairly general type of selection procedure that is particularly applicable to plant

selection. The problem is to reduce in  $k$  stages an initial set of  $N$  candidates to a predetermined fraction,  $\pi$ , called the "selection intensity," using a fixed total expenditure of resources,  $A$ . At stage  $r$  ( $1 \leq r \leq k$ ), the candidates selected at stage  $r-1$  are tested, using resources  $A_r$ , to obtain for each a score,  $X_r$ , which estimates  $Y$  with a precision dependent upon  $A_r$ ; the fraction,  $P_r$  ( $0 < P_r \leq 1$ ), having the highest scores are selected, and the remainder are discarded. Stage 0 consists in selecting at random a fraction,  $P_0$ , of the initial set. The problem is to choose  $P_r$  and  $A_r$  to maximize the expected mean  $Y$ -value in the selected group, subject to  $A_1 + \dots + A_k = A$  and  $P_0 P_1 \dots P_k = \pi$ , where  $A$  and  $\pi$  are given. The authors found that approximately optimum results were obtained with  $A_r = A/k$ ,  $P_r = \sqrt[k]{\pi}$ , for  $r = 1, \dots, k$ , called the "symmetric" scheme, usually with  $P_0 = 1$ , although in some circumstances a value  $P_0 < 1$  effected further improvement. Three or four stages at most were sufficient.

In the context of plant selection, the  $N$  candidates are the new crop varieties produced in a particular year, and the resource expenditure,  $A$ , is the area of land available for testing, which must be divided into separate portions for varieties being tested for the first time, varieties selected on the basis of last year's tests to be tested in stage 2, and so on. For example, suppose  $N = 200$  varieties are started in a two-year program to select 8 to compare with the standard commercial types (thus,  $\pi = .04$ ). Then at the end of each year,  $\sqrt{.04} = \frac{1}{5}$  of the varieties should be selected—that is, 40 at the end of the year 1 and 8 at the end of year 2—with equal areas of land to be divided among the 200 varieties in year 1 and the 40 varieties in year 2.

**Drug screening.** In drug screening, the problem is to screen a large supply of chemical compounds by means of a biological test, usually in laboratory animals, in order to select for further testing the few that may possess the biological activity desired. Here  $Y$  stands for the unknown activity level of a compound (averaged over a conceptual population of animals), estimates being provided by the test results,  $X_1, X_2, \dots$ . The distribution of  $Y$  in the population of compounds available for screening will usually have a large peak at  $Y = 0$ , since most of the compounds do not possess the activity being sought unless a specific class of compounds chemically related to known active compounds is being screened. The number of compounds available for testing usually exceeds the capacity of the testing facilities; therefore, part of the problem in drug screening is to determine the optimum number,  $N$ , of compounds to screen in a given period of time.

The mean  $Y$  in the selected group does not have as much relevance in drug screening as it does in plant selection. Instead, a value,  $a$ , is usually specified such that a drug is of interest if its activity equals or exceeds level  $a$ . The screening procedure is then designed to maximize the number of compounds in the selected group having  $Y \geq a$ , usually subject to the requirement that the total number of compounds selected over a certain period of time is fixed. Davies (1958) and King (1963) have considered in detail this approach to the statistical design of drug-screening tests.

**Educational selection.** The consideration of selection procedures to allocate school children to different "streams" is necessarily much more complex than in the applications considered above. For one thing, there can be no question of rejection; the object, at least in principle, is to provide the education most suitable for each child. Furthermore, it can be expected that the characteristic  $Y$  of each child will be altered by the particular stream in which he may be placed. An admirable discussion of the problems was given by Finney (1962), who described, as an illustration of the methodology, a simplified mathematical model of the educational selection process then in operation in the British school system.

Finney considered university entrance as a two-stage selection process: the first stage is the separation of students at the age of 11+ into those who will receive a grammar school education and those who will go instead to a secondary school, and the second stage is university entrance. Denoting by  $X_1$  the composite score of all test results available at the first stage, by  $X_2$  the composite score at university entrance, and by  $Y$  the "suitability" of a student for university study as determined by his subsequent university grades, Finney considered  $Y$ ,  $X_1$ , and  $X_2$  to have a multivariate normal distribution with correlation coefficients estimated from available data. He studied the effects that varying the proportion of students admitted to grammar school, as well as the relative proportions admitted to universities from the two types of school, had on the average value of  $Y$  in the selected group and on the proportion of university entrants having  $Y \geq a$ . Interesting numerical results are presented, but the main feature of the paper is its demonstration of how the approach can bring about a clearer insight into the issues involved in a selection process.

#### The case where $N$ is small

Rather different methods of approach have been developed for selection when the number  $N$  is small

enough so that the individual values of  $Y$ , rather than their distribution, may be considered. The object of the selection procedure is expressed in terms of the  $Y$ 's; for example, the object may be to select the individual with the largest value of  $Y$ , to select the individuals with the  $t$  largest values, or to rank the  $N$  individuals in order according to their values of  $Y$ . These are special cases of the general goal of dividing the  $N$  individuals into  $c$  categories, containing respectively the  $n_c$  individuals with the highest values of  $Y$ , the  $n_{c-1}$  individuals with the next highest values, and so on, down to the  $n_1$  individuals with the lowest values of  $Y$ . Bechhofer (1954) developed expressions for the probability of a correct assignment of the  $N$  individuals to the  $c$  categories.

Selecting the "best" of  $N$  candidates. Of most frequent interest in practical applications is the selection of the best of several candidates, "best" being interpreted to mean the one with the largest  $Y$ . Estimates of the unknown  $Y$ 's are obtained from experimentation, and the problem usually is to decide how much experimentation needs to be done.

In a single-stage selection procedure, an experiment consisting of taking  $n$  observations for each candidate is performed, and the candidate with the highest observed mean is selected. The probability of a correct selection is the probability that the candidate with the highest  $Y$  will also have the highest observed mean value; this is a function not only of the number  $n$  of observations but also of the unknown configuration of values of  $Y$ .

Bechhofer (1954) recommended that the experimenter choose  $n$  so that the probability of a correct selection would exceed a specified value,  $P$ , whenever the best value of  $Y$  exceeded the others by at least a specified amount,  $d$ . His paper contains tables of the required value of  $n$ , calculated on the assumption that the  $Y$ 's are in the "least favorable" configuration, which in this case is the configuration where all the  $Y$ 's except the best one are equal and are less than the best one by the amount  $d$ .

Another approach to determining the value of  $n$  is based on striking an optimum balance between the cost of taking observations, which is a function of  $n$ , and the economic loss incurred if some candidate other than the best one is selected. The loss due to an incorrect selection is assumed to be a function, usually linear, of the difference between the largest  $Y$  and the selected  $Y$ . With the probability of selecting any particular candidate taken into account, an expected loss or risk function, which is a function of  $n$  and the unknown  $Y$ 's, is determined. Somerville (1954) showed how the minimax principle can be used to determine the

optimum sample size; this procedure is appropriate if no prior information is available about the unknown  $Y$ -values [see DECISION THEORY]. In the case where prior information is available, Dunnett (1960) showed how such information can be utilized in determining the sample size; he also made numerical comparisons between alternative procedures.

Gupta (1965) considered the situation in which the experimenter is willing to select a larger group than is actually needed and is concerned with guaranteeing a specified probability,  $P$ , that the best candidate is included in the selected group. In this way, the need to specify a minimum difference,  $d$ , as in Bechhofer's method, is avoided, but there is the drawback of not necessarily having a unique selection. Gupta investigated the effect of the sample size,  $n$ , and the configuration of the  $Y$ 's on the expected size of the selected group.

Sequential procedures have also been investigated; for example, Paulson (1964) considered a sequential method for dropping candidates from contention at each stage until only one remains, so as to achieve a specified probability,  $P$ , that the best one is selected whenever its value  $Y$  exceeds the others by at least  $d$ . [See SEQUENTIAL ANALYSIS.]

**A medical selection problem.** An interesting method (Colton 1963) for selecting the better of two medical treatments uses some of the principles discussed above but also contains ingenious points of difference. In the problem considered, there is a fixed number of patients to be treated. A clinical trial is performed on a portion of them, with equal numbers being given each treatment. On the basis of the trial, one of the two treatments is selected to treat the remainder of the patients. The problem is to determine how many patients to include in the trial in order to maximize the expected total number receiving the better drug. Sequential procedures for making the selection are also discussed.

## Tournaments

A tournament is a series of contests between pairs of  $N$  players (or teams) with the object either of selecting the best player or of ranking the players in order. It may be regarded as a selection procedure in which the experiments consist of paired comparisons between candidates. David (1959) studied some properties of two types of tournaments, the knockout and the round robin. Glenn (1960) compared the round robin and several variations of the knockout tournament for the case of four contestants; he found that a single knockout tournament with each contest being on a "best two

out of three" basis achieved the highest probability that the best player will win, but at the "expense" of requiring a higher average number of games.

## Other problems

There are many other interesting topics in screening and selection. One is *group screening*, in which a single test is performed on several candidates as a group to determine whether any of them possess the characteristic of interest. When an affirmative answer is obtained, further tests are performed to determine which ones possess the characteristic. One application of this procedure is in blood testing for the presence of some disease; a great saving in the number of tests necessary is accomplished by physically pooling several samples and making a single test. Another application is in factor screening in industrial research (see Sobel & Groll 1959; Watson 1961).

In practice, many screening problems are multivariate—that is, there is more than one trait,  $Y$ , of interest, and the traits are likely to be correlated. Sometimes the measurements on the several traits are reduced to a single variate by combination into a suitable index, perhaps with weights determined by the economic worth of each trait. Sometimes only one trait is dealt with at a time, the candidates considered for selection on the basis of trait  $Y$ , being those who have previously been selected on the basis of  $Y_1, \dots, Y_{r-1}$  in turn. Much work remains to be done to determine the best procedures for use in multivariate screening. (See Rao 1965 for a treatment of some of the mathematical problems.)

## SEASHORE, CARL E.

Carl Emil Seashore (1866-1949), psychologist and leader in the development of American graduate education, was born in Morlunda, Sweden, where his family had been farmers for several generations. His parents migrated to Boone County, Iowa, in 1869, settling on an 80-acre farm in a Swedish community. Seashore's father acted as a lay Lutheran preacher and served as carpenter and cabinetmaker; he also had a considerable interest in music.

Seashore's early education, in Swedish, included the memorization of chapters of the Bible, a cherished feat in Sweden. At the age of 13 he went to live in the home of a Lutheran pastor "to improve his English, manners, and music." A year later he

became a church organist. He helped to run his father's farm for a few years and then attended the Lutheran college Gustavus Adolphus at a time when, according to his autobiography, "within an area of fifty square miles around our home only one man had gone to college . . ." (1930, p. 240). He received his A.B. in 1891.

Seashore went on to Yale to study philosophy with George T. Ladd, who introduced him both to the new branch of philosophy called experimental psychology and to Edward W. Scripture, a new faculty member not much older than Seashore. Seashore, nearing 26, was stimulated by working both with a mature scholar like Ladd and with Scripture, who after studying at Leipzig with Wundt had come to Yale to start a psychology laboratory. In Seashore's five years at Yale a three-fold foundation for his career as a psychologist was built. First, as Scripture's research assistant, he shared the problems of developing the laboratory course for psychology. In the laboratory he experimented in classical, physiological psychology through studies of visual accommodation time, perception of pressure and weight, and the laws determining illusions and hallucinations. He worked with Scripture on a spark chronometer and an audiometer. Second, in Ladd's seminar he undertook to defend the point of view that whereas evolution holds sway in all organic life, it does not apply to mental life. His conclusions, however, turned out to be the opposite of his initial hypotheses. Thus he developed a scholarly logic and a scientific Darwinian philosophy.

While at Yale Seashore lived with a Swedish family and attended the Lutheran church. Here the third element of the foundation for his career was developed. Although unwilling to preach sermons, he at times lectured the congregation on the relationship of philosophy and psychology to everyday life and developed a form of presentation understandable to an intelligent but untrained audience.

In 1895 he received his Ph.D. and spent that summer visiting psychology laboratories in France and Germany. He then returned to Yale as a fellow in psychology.

Two years later Seashore became assistant professor of philosophy at the State University of Iowa and thus an associate of George T. W. Patrick, professor of mental and moral philosophy and didactics at Iowa since 1887. Having taken work in psychology at Johns Hopkins with G. Stanley Hall, Patrick favored a strong development of the subject at Iowa and had set aside funds with which to build up a laboratory. Seashore developed several

important pieces of apparatus for use in a laboratory course and for research studies. This original equipment soon made the Iowa Psychology Laboratory prominent in the profession. Of special note was the equipment designed for the study of musical abilities.

In addition to his five papers on the problems of perception, published while he was at Yale, Seashore published papers in the University of Iowa Studies in Psychology, ten of them by the time he was promoted to professorial rank in 1902.

In 1905 he became chairman of the department of philosophy and psychology, succeeding Patrick. Under Seashore's chairmanship, the department increased the number of higher degrees awarded. This strong interest in promoting graduate work led to his appointment, in 1908, as dean of the graduate school. In addition, he served as chairman of a committee on the teaching of psychology appointed by the American Psychological Association and in 1911 as the association's president.

Seashore was a national leader in the field of graduate education as well as psychology. Under the auspices of the National Research Council, for example, he originated and carried out a project for gifted students, arguing that colleges and universities should devote as much attention to gifted students as to poor ones. He traveled widely both in his capacity as dean and in his efforts on behalf of the gifted student. Yet during this entire period he continued to do research and to publish.

He saw possibilities for the enrichment of teaching and research by developing the psychological aspects of several fields of learning and human welfare. A psychological clinic was established to supplement the services undertaken by the local psychiatric hospital. Collaboration with the speech department resulted in a speech clinic. Seashore initiated and supported an experimental approach to many problems associated with the Iowa School of Music, and a section for applied psychology of music was organized. Similar developments took place in graphic arts, plastic arts, and physical education.

Among Seashore's honors were several honorary degrees, including an sc.D. from Yale in 1935 and an Mus.D. from the Chicago Musical College in 1939. He was elected to the National Academy of Sciences and was a member of the Acoustical Society of America and the American Musicological Society, among others. He was also an honorary fellow of the British Psychological Society.

## SECHENOV, IVAN M.

Ivan Mikhailovich Sechenov (1829–1905), Russian physiologist, neurologist, and founder of objective physiological psychology, was born the son of a small landowner in the village of Tyoply Stan (now Sechenovo) in Simbirsk Province (now Arzamas Region). Taught first by private tutors, he mastered German and French in addition to Russian. At 14 he entered the St. Petersburg Military Engineering School. He served from 1848 to 1850 as a field engineer in a Kiev brigade. Then he resigned his military commission and from 1850 to 1856 studied medicine at the University of Moscow. He spent the next three and a half years doing post-graduate research and studying physiology, chemistry, and physics at Berlin, Heidelberg, Leipzig, and Vienna. Among his teachers were Johannes Müller, Emil DuBois-Reymond, Hermann von Helmholtz, Carl F. W. Ludwig, Robert W. Bunsen, and Heinrich Magnus.

Sechenov returned to Russia in 1860 to become at first adjunct and then full professor of physiology in the St. Petersburg Medico-Surgical Academy. Ten years later he resigned from that institution, giving as the reason, according to his *Autobiographical Notes* (1907), his distaste for its administrative policy and citing specifically the veto of his proposal to appoint Ilya I. Mechnikov to a vacant chair. (Mechnikov presumably was turned down because he was a Jew; later, in 1908, he won the Nobel prize.) For a while, Sechenov was without a professorial position and worked in the chemistry laboratory of his friend Dmitri Mendeleev, but he was soon appointed professor of physiology at the University of Odessa. He left that university in 1876 for the University of St. Petersburg and stayed there until 1888, when he resigned—alienated again by the academic atmosphere of St. Petersburg—and in 1889 moved finally to the University of Moscow.

In 1862 Sechenov took a year's leave to do experimental work in the laboratory of Claude Bernard at the Collège de France. There he discovered "central inhibition," namely, that spinal reflex movement may be "inhibited"—diminished or stopped—by the stimulation of higher-neural inhibitory centers. Further experimentation led to the important conception of higher-neural action as an interplay of excitation and inhibition. [See NERVOUS SYSTEM, article on STRUCTURE AND FUNCTION OF THE BRAIN.] This view was taken over wholly by Pavlov and more recently has won increasing acceptance as a result of direct microelectric neural

probing. Sechenov's report on inhibition was published in German and French (1863a).

Sechenov's physiological contributions soon became part of Western science. This is not true of his psychological essays—"Reflexes of the Brain" (1863b), "Who Must Investigate the Problems of Psychology, and How" (1873a), "Elements of Thought" (1878), and a number of others—which presaged the systems of psychology of Pavlov and Bekhterev and radically affected the world views not only of such distinguished men of science as Mendeleev, Mechnikov, Vladimir O. Kovalevskii, and Arkadii K. Timiriyazev but also of such widely known men of letters as Turgenyev, Gorki, and Tolstoi. Translated in part into French in 1884 and into English only in 1935, the radical Sechenov system of psychology was for years almost unknown outside Russia and had no influence whatever on Western and American thought in the field, from Wundt through James to Watson and the neobehaviorists. Only in 1950, in the second edition of Boring's *A History of Experimental Psychology* (1929), is Sechenov first mentioned in English in any significant sense. Recently, in *A History of Psychology*, by Esper (1964), a nine-page passage is devoted to his contributions, and it is asserted that Sechenov "wrote the first 'objective' psychology and became the first 'behaviorist' of modern times" (p. 324).

Briefly stated, Sechenov's psychological system rests on five interrelated theses:

(1) A consistent physical monism: Sechenov held that psychology will become a science only insofar as it studies the muscular and neural action of the psyche. He asserted that no "conceivable demarcation [from a scientific point of view] can be found between obvious somatic, i.e., bodily, nervous acts and unmistakable psychical phenomena" (1873b, p. 151).

(2) Physiological and psychical reactions are both considered to be reflex actions: in Sechenov's words, "All movements bearing the name of voluntary in physiology are reflex in a strict sense" ([1907] 1965, p. 109), and a thought "is the first two-thirds of a psychical reflex" ([1863b] 1935, p. 321).

(3) The reflex as the mechanism of association: "An association is," according to Sechenov, "an uninterrupted series of contacts of the end of every preceding reflex with the beginning of the following one" (*ibid.*, p. 312). The actual experience of an event and the memory of it are both represented by identical psychical reflexes but are evoked by different stimuli.

(4) The psychic as associative in genesis and central neural in mediation: perception and ideas emerge from associations of reflexes and their integration in the sensory sphere; both association and integration are mediated by the central nervous system.

(5) A radical environmentalism: the largest part of thoughts and ideas, 999 parts out of 1,000, as Sechenov would have it, derives from training, and only a minimal part is due to heredity.

Of these five theses, the first and last do, of course, have roots in earlier Western thought; the middle three are essentially original contributions by Sechenov.

## SECTS AND CULTS

The term "sect" is used in the sociology of religion to designate a particular kind of religious group. This usage is both more precise and more technical than the use of the word in everyday speech. It is part of a typology of religious groupings which has been found useful in the study of religious movements and bodies. The term "cult" has also been given a special technical meaning as part of this typology, but it has remained less precisely defined, less useful, and less used in empirical research.

### Church and sect

In his study of the relationship between Christianity and the world, Ernst Troeltsch (1912) examined the tensions, problems, and dilemmas that confronted the Christian church as it attempted to come to terms with four aspects of classical civilization: family life, economic activity, politics and power, and intellectual endeavor. He found this history characterized by two major tendencies which exhibited themselves in varied forms over a long period of time. The first was the tendency to come to terms with secular society and culture, although often with considerable qualification, and generally to compromise with the world; the second, a highly significant rejection by a minority of the whole spirit of compromise and an opposition to important aspects of the secular culture and its institutions. These tendencies found organized expression in two basic and contrasting sociological types, which Troeltsch called the *church* and the *sect*.

The *church* represents the majority reaction and involves within its structure considerable variation of accommodation and compromise. It defines itself as the established expression of the relation between God and men, the institutional channel of divine grace, whose mission it is to enter the world in order to sanctify it. Thus, the church attempts to dominate the world with its values and is eventually dominated by the world to one extent or another. The church is characterized by what is vir-

tually membership on the basis of birth for the children of believers, although formally all are members through baptism. Thus, the practice of infant baptism is characteristic of churches, and churches become educational agencies. The church is the means for the administration of grace and exhibits the theological and sociological concomitants of this function: dogma and hierarchy. It is universal in its aspirations and addresses itself to the conversion of all. Consequently, its social structure is inclusive and often coincides with geographical or cultural entities or, as in the Middle Ages, with a whole civilization—Christendom.

The *sect*, as defined in the sociological literature since Troeltsch, represents a contrapuntal ideal type to the church form of social organization. It is a voluntary society of strict believers who live apart from the world in some way. Its foundation upon contracted or upon freely elected membership marks a sharp contrast with the ecclesiastical body of the church, as does its smallness of size and its spirit of austerity and asceticism. The sect expresses defiance of the world or withdrawal from it, a greater or lesser rejection of the legitimacy of the demands of the secular sphere. It emphasizes a conversion experience prior to joining. Sociological theory presents the church as the ideal type of religious body accommodating to the world and the sect as the ideal type of the protest group, protesting both the church's accommodation to the world and the world itself. The sect's refusal to compromise with secular values and institutions may find expression in either an active or a passive form. Hence there are two fundamental sect types: the militant oppositionist sect, which is active in its antagonism to the world, and the passive sect, which prefers withdrawal to militant defiance.

**Accommodation of sects.** H. Richard Niebuhr (1929), Liston Pope (1942), and others have delineated the sequential pattern in the course of which sects themselves are accommodated to the secular society and make their own compromise with the world. The birth of children to the sectaries, the better adjustment to conditions of life, including an increasing prosperity, and the passage of time itself—all contribute to a routinization of the sect into an established sociological entity which has accepted the social world in which it exists. Niebuhr observed that the sect, if defined rigorously in the terms presented here, cannot last beyond the founding generation. Pope's study would indicate that often considerable accommodation occurs in the lifetime of the founding generation. The routinized sect has been given the

name of *denomination*. Here once again, as in the use of the term *sect*, a word of common speech is given a more precise and technical designation. The typical picture presented in a number of sociological studies is that of the establishment of sects as protest groups against accommodation to the world and then their gradual acceptance of the world and their routinization as a reconciled part of it. This process is often associated with increasing wealth and respectability for the membership, in part at least the fruit of their ascetic and austere sectarian behavior.

**Established sects.** However, the work of J. Milton Yinger (1946) and Bryan R. Wilson (1959; 1961) has shown that not all sects, by any means, go through this sequence from sect to denomination and lose their earlier spirit of militancy and segregation. Some sects are successful in maintaining themselves over a long period of time in an established condition of opposition, or at least nonacceptance, with respect to secular society and its values. They become *established sects*, which, despite changes in their composition and milieu and the passing of the founding generation, retain a sectarian organization and an antagonistic or withdrawn posture in the face of the world. Of these established sects two types may be seen. There are those which secede from the world in a literal geographic sense and live in a territorial isolation in which they attempt to establish total communities after the model of their own values. The Amish, Hutterites, and others offer examples. There are also established sects such as the Jehovah's Witnesses and Christadelphians which remain within the general urban society and which nevertheless successfully maintain their opposition to it. Although such groups have not separated themselves geographically, they are separate in less palpable but not any less real ways, and they succeed in keeping their membership apart from genuine, intimate nonsectarian social participation.

**Sect ideology.** All sects display a considerable degree of totalism in dominating the lives of their membership. Ideological domination is usually supplemented and supported on the social level by measures which set the group apart, such as endogamy, limitations on the forms of participation with outsiders, refusal to take part in significant common societal activities (military service, saluting the flag, or medical practice), peculiar habits of eating and abstinence, and with some groups, even peculiarities of dress. Related to these social forms of segregation is the notion of the sect members as comprising the "elect," some kind of religious elite.

### Social bases of sectarianism

Sects are opposition groups, and they arise in opposition to the accommodation of churches or developing denominations, in rejection of some other aspects of their milieu, or in some combination of the two. Troeltsch has shown that the sect form asserted itself early in the Middle Ages. It is to be seen in the period of the Gregorian agitation (c. 1080) when the sectarianism of the Albigensians spread in Italy and France. This movement had complex social and religious sources. It was greatly affected by the reform efforts and struggles of Pope Gregory VII; it expressed the opposition of the devout laity to what they considered immorality and simony in the church; and it also represented the aggressive reaction of new urban classes against the established order in both church and city. This correspondence and interpenetration of religious and social interests has often been found associated with the origin and formation of sects. It has often been observed in the sociological literature that the sect is a lower-class protest phenomenon.

The conditions of life of different social strata influence the psychological make-up and need dispositions of their members. Consequently, social classes and strata develop different religious needs and sensibilities. Niebuhr stated that the religion of the disinherited may be observed in the rise of many sects and that Christianity was at first the religion of those who had little stake in the civilization of their time. Troeltsch concluded that all really creative religious movements are the work of lower strata. Niebuhr stressed the importance of economic success in the transformation of protesting sects into denominations and pointed to the fact that the churches of the poor sooner or later become churches of the middle class.

**Functions of the sect.** The sect exhibits complex functions in society. It often offers an outlet for strains and frustrations incumbent upon lower-class status and for the condition of being socially and economically disinherited. In allowing catharsis, it at the same time provides a meaningful community, together with a set of values that promotes a personal reorganization of the members' lives and often their eventual reincorporation into the general society. Not only may the sect reconcile the disinherited to their situation through the various compensations of this-worldly community and other-worldly expectations, but it may also bring new meaning to them in its reinterpretation of their life experience. In doing this it may socialize its members in virtues which lead to economic and

worldly success. Moreover, the sect, with its close community of human beings and its new values which give meaning to life, offers a way out of anomie to many who have been disorganized in the impersonal milieu of the modern city. When the founding generation passes away, the established sect continues to perform similar functions for individuals who are attracted to it and provides for its born members the setting for acting out their established values. Sects may take on a number of new functions when their social composition and their specific social situation change over time.

When established organizational conditions offer insufficient expression to the religious needs of people or when established institutions fail to meet needs of particular strata and groups at all, it is easy for charismatic leaders to arise and organize a following. Such developments issue in movements of protest of a marked sectarian character. The charismatic leader as a rallying focus and an active initiator plays a strategic role in the origin of sects and often impresses his own self-interpretation upon the group as the model for its behavior and beliefs. The accommodation and routinization of churches and the development of sects into denominations is often the occasion for schism, which is an important source of sectarian movements. Moreover, conditions and social change within the general society, altered economic status for particular groups, urbanization, increased mobility—geographic and psychological—and other phenomena associated with industrialization all contribute to the rise of sects.

The sect as a sociological ideal type is therefore to be understood as the embodiment and expression of rejection of some significant aspect of secular life. It represents a protest against compromise with the society and its values and the institutional development of the church itself as an aspect of this accommodation. It is charismatic, lay, egalitarian, and voluntaristic religion in contrast to the established, professional, hierarchical, and ascribed religion of the church. In this typology the sect represents an ideal type: empirical reality and specific historical development present a greater variety than does the typology itself.

### Allied types of religious protest

Many protest movements display sectarian characteristics but to different degrees and often in somewhat different respects. Most of the important protest movements in Christianity, while highly influenced by sectlike elements, endeavored to achieve organizational forms which also involved many of the characteristics of the church. Thus the

Reformed churches of the Protestant Reformation vary along a complex continuum from Anglicanism with its episcopate and quite ecclesiastical structure, at one end, to the sectlike organizations of the Baptists, at the other, with interesting combinations of church and sect attributes characterizing the in-between groups, for example, the Churches of the Standing Order in colonial Massachusetts. Joachim Wach (1944) has called a number of them *independent groups* and has pointed out that they vary in form from churchlike hierarchical structures to egalitarian covenants of laymen.

However, not all protest is secessionist in intention, nor does protest necessarily issue in separate organization outside the established bodies. Monasticism and the later religious orders offer an outstanding example of protest groups which remain within the older ecclesiastical body. Monasticism exhibits a number of sectarian qualities: it establishes a separate community, practices austerity and asceticism, and employs segregating rules and peculiarities of dress. Like the geographically isolated sects, it creates its own distinct community but remains dependent upon the larger body for replacement of personnel. In its origin Christian monasticism was both a protest against the accommodation of the church and a rejection of the world. Its relationship to the sacramental church was ambiguous, and it could have become a secessionist movement. But in the rule of Basil in the East and of Benedict in the West, it was reintegrated formally and solidly into the structure of the church. Here it continued to play a role of witness and to advocate reform. Moreover, it placed its enormous energy at the disposal of the church for missionary and other activity. In the High Middle Ages, the Franciscan movement represented a similar tendency. It was contained within the church at first by the personal character of its founder. Later on, its integration into the church was the cause of a great struggle in which both schism and heresy as well as reintegration of the order into the church resulted. Moreover, the routinization process from sect to denomination is also found in the history of religious orders. Such routinization is often the cause of schism and divisions and the rise of reforming leaders of the charismatic type.

**The Mormons.** A religious body of a marked sectlike character which seeks geographical isolation may, when circumstances are propitious, develop into an entity resembling an ethnic group or even a nation. The Mormons, a sectlike group choosing to imitate the Biblical model of Israel, found themselves in circumstances where such recapitulation took on realistic significance. Perse-

cuted and driven from their settlements, achieving victories and suffering defeats, the Mormons built up in a decade and a half a folk tradition and mentality of their own. In moving to the West they found a vast unoccupied expanse of land upon which they could expand their vision of an earthly kingdom of God to imperial dimensions. As a result the semiecclesiastical organization which developed was at the same time the organized core of a Mormon people held together by kinship ties, common beliefs and values, a common history of achievement and suffering, and a common homeland. The Mormon "Zionism" of the nineteenth century had led to a development from near sect to near nation. When the Mormons applied for admission of their state of Deseret to the federal union, they attempted to find a political form for their achievement which stopped just short of nationhood; and in times of stress and conflict, frankly separatist sentiment was widespread (O'Dea 1954). Churches have also become the core of ethnic groups, as under the Turkish millet system in the Middle East, which granted a degree of political autonomy to religious communities.

### Typological study of sects

Wilson has shown that it is possible to distinguish types of sects on the basis of their ideological orientations. He does this within the context of Protestantism on the basis of the sect's self-definition, specifically its conception of its calling and mission. He distinguishes first the *conversionist sect*, which seeks to convert others and thereby to change the world; second, the *adventist sect*, which expects drastic divine intervention and awaits a new dispensation; third, the *introversionist sect*, which is pietistic in its orientation, withdrawing from the world to cultivate its inner spirituality; and the *gnostic sect*, which offers some special esoteric religious knowledge. Such sects will experience the effects of routinization differently and will also exhibit different structural tendencies to some degree (Wilson 1959; 1961).

Moreover, since the terms *church* and *sect* are ideal-typical constructions, what is observed in real life situations only approximates the specifications of the theoretical definitions. Such ideal-typical concepts have an analogical character and are most useful for observation, analysis, and interpretation when utilized with flexibility. This analogical character of the Troeltschian concepts is best seen in the behavior of churches when placed in circumstances which elicit sectlike behavior from them. The Roman Catholic church in the United States in the nineteenth century found itself a minority

religion, largely lower class in character, constituted in its vast majority by ethnic groups of recent immigrant origin, and therefore of lower prestige in the general American society. Moreover, the value system of American society was largely derived from Protestantism, and the various forms of Protestantism constituted something like an unofficially established national religion. The Roman Catholic church responded by separating itself from the surrounding Protestant world in a wide range of activities and by constructing its own institutional contexts for education from the primary grades through the university, for social welfare work, for hospitals and other institutions for aid, and for sports and entertainment. Moreover, the mentality of American Catholics took on a number of sectlike attributes, such as apartness and defensiveness, rigorism in morality, and militancy in religious identification. While this situation was in part conditioned by the defensive character of post-Tridentine Catholicism in Europe and by the Irish background of so many American Catholics, there is no question of the importance of American conditions in bringing about a sectlike result. It is significant in this connection that the first heresy conflict in many decades to be seen in American Catholicism concerned a student center at Harvard University which displayed a militant sectarian response to secularism in the intellectual sphere and against the church's accommodation to the secular world. This group ended in heresy and excommunication (O'Dea 1961).

What has evolved from the time of Troeltsch is a typology of religious groups which has proven its utility in description and analysis in the sociological study of religion. It may be summarized briefly as follows: The *church* is the embodiment of institutional religion and accommodation to the world. It gives rise to protest groups and movements. These may vary from *reformed churches* to *independent groups* to *sects*, or they may give rise to groups which remain within the older body, affecting and reforming it in various ways. Sects may be either actively in opposition or passive and withdrawing with respect to the world. They may be geographically isolated, or they may exist within the general society, practicing forms of social separatism. Sects may go through a process of social mobility and routinization and develop into *denominations*, accepting in one way or another the secular society and its values. The sect may also institutionalize its oppositionist character and become an *established sect*. Under propitious circumstances a sect or near sect can develop into a

new ethnic or quasi-ethnic entity; it can become a *people*.

While this typology has been useful and represents the contributions and insights of a number of sociologists and scholars, it remains unsatisfactory. Like all ideal type concepts, it is unwieldy to use in analysis and possesses severe limitations with respect to refinement or adaptation to mathematical use. What is necessary is to analyze these ideal-typical constructs and to state their components in terms of factors or variables. This would mean replacing the global concept with a number of dilemmas or choice points which give rise to one kind of organizational tendency rather than another or, in a like manner, breaking up the ideal types into tendencies which vary from group to group along a series of continua. A similar kind of analysis was made by Talcott Parsons with respect to the ideal type conceptions of Tönnies (*Gemeinschaft and Gesellschaft*), which he broke down into five pattern variables. Such factors or variables would make it possible to compare groups with respect to a number of characteristics instead of the present, more cumbersome process of using ideal types as an analytical model.

**The cult.** To this already complex typology, von Wiese and Howard Becker (1932) have added the *cult*. While this term has been less clearly defined, it has been most generally used in the scholarly literature to designate a more loosely organized and more individualistic group than those already discussed (this usage must be distinguished from the scholarly use of the word *cult* to refer to the ritual act of worship). Based on individual concerns and experiences, the cult is often transient, its membership often highly fluctuating. Belonging to the cult often does not involve an acceptance of common discipline and need not necessarily preclude membership in other kinds of religious groups. Both theosophy and New Thought have been labeled as cults. Wilson (1961) considers the cult a gnostic sect and, in his study of Christian Science in Great Britain, shows a group that combines aspects of bureaucratized organization with characteristics of both sect and cult.

What is involved in this type of group may be best understood by returning to Troeltsch's original treatment, with which this article began. American sociologists have tended to make only a partial use of the paradigm of analysis introduced by Troeltsch and to develop only the implications of the church-sect dichotomy.

Troeltsch, however, emphasized another kind of religious reaction to accommodation to the world

and routinization in the development of religious forms of expression. He speaks of *mysticism*, which is found particularly when the formalization of worship and doctrine makes individual religious experience difficult and unfruitful within the established forms. Just as the sect tends to be a lower-class phenomenon (the religious form of those without a stake in the social system), so mysticism is characteristic of the educated classes. It has been an element enriching the life of the established religious bodies, as it has also been an expression of protest against them. It is of great significance in the development of the religious life of the Catholic church and was a tremendously important element in the Reformation and in post-Reformation Protestantism. When it does affect the lower classes and when found in religious movements of the poor, it often involves emotional excesses and a taste for heterodox novelties. The religious experience of worship and a relationship to the Deity, the gnostic experience involving secret knowledge and skill not available to all, and the mystical effort to achieve a personal relationship with God outside the established forms of worship and even of language are all obviously related. Consequently, some element of mysticism may be found in varied versions of the religious experience, although religious traditions placing their emphasis upon law often discourage mysticism, evidently fearing its antinomian possibilities.

**Sects in non-Christian cultures.** Most of the work on sects in the sociological literature concerns Christian groups. It is obvious, however, that the typology refers to aspects and characteristics of religious groups and movements to be found outside the Christian tradition. Wach has pointed out that Zoroastrianism and Mahāyāna Buddhism have produced ecclesiastical bodies which fit the Troeltschian definition of the church in its main outlines and that groups in Islam and Confucianism have evolved semiecclesiastical bodies. Monasticism has been developed in a number of quite different religious and cultural traditions. Sects which fit many of the characteristics we have presented above may also be found in the other world religions. For example, in Islam the rise of Wahhabism represents an active oppositionist sect, while Bahai arose as a sect of the passive withdrawing character.

**Sectarianism in politics.** Finally, it should be noted that the typology given here is to some extent applicable to organizations other than those of a religious character. Groups with situationally transcendent ideals seem to display similar organ-

izational types. This may be seen in political parties with some degree of utopianism in their programmatic aspirations. For example, social democratic parties in Europe were formed upon situationally transcendent ideals and in opposition to existing conditions. A degree of success both for membership and officialdom led to a process of routinization and accommodation analogous to that experienced by a church in the religious sphere (Michels 1911). As a consequence, protest movements developed, such as the Spartacus group in Germany, or even the Third International. Thus, the basic variables involved in this typology would appear to be found whenever organized expression of interests based upon situationally transcendent aspirations occurs.

## SECURITIES MARKETS

Securities markets exist in more than sixty countries and on all continents. They have grown in number and importance with the increase in the number and size of corporations, the volume of government debt instruments, and the diffusion of ownership of corporate and government securities.

Securities markets are organizations of security

dealers and brokers whose operations reduce the cost of transferring ownership of government and corporate bonds and stocks and increase the liquidity of these assets. The reduction in transaction costs is achieved by the specialization of these organizations in transmitting information relevant for the decisions of potential buyers and sellers, by the provision of standardized contracts with respect to their purchase, sale, and financing, and frequently by furnishing specialized facilities for the execution of security transactions. Securities markets—especially organized exchanges—increase the liquidity of securities by providing almost continuous information regarding market prices, maximum bids, and minimum offers. Liquidity is increased in the sense that owners of securities can have greater knowledge of the current market value of their securities. This reduces the risk of incorrectly assessing the value of one's securities. This increase in liquidity is important not only for holders of existing securities but also for issuers of new securities who are raising capital for their enterprises.

Securities markets, especially those operating through major exchanges, have some of the characteristics of perfectly competitive markets. The things that are bought and sold—shares of common stock of the General Motors Corporation, for example—are perfect substitutes for each other, and the dissemination of information on market prices is accurate, extremely rapid, and very widespread. Information relevant for appraising the prospects of a corporation is also widely available. Further, there are many buyers and sellers, most of whom buy and sell in quantities insufficient to have a significant impact on the price. Although large institutional investors can temporarily raise the price of shares of even very large corporations by placing large "market" orders (and conversely depress the price of shares by selling), this impact can be greatly diminished by spreading the orders over a period of time. The liquidity of even very large holdings of common stock was dramatically illustrated in recent years by the sale of millions of shares of Ford Motor Company stock by the Ford Foundation with no apparent large impact on prices.

Security prices are highly sensitive to information bearing on the prospective profitability of the corporations whose shares are involved. The opportunities to profit from changes in the prices of securities have attracted the attention and the money of millions of investors and speculators and have generated many points of view about ways to predict future security prices. The numerous points of view fall into two general categories: (1) efforts

to predict the profitability of firms by forecasts of general business conditions, by forecasts of costs, revenues, and profits for particular industries, and by analyses of the competitive position of particular firms, and (2) efforts to predict future prices by an analysis of the historical course of prices themselves. This latter point of view has been subjected to considerable analysis by academic economists and statisticians (Cootner 1964), and the predominant view among academic economists is that historical analyses of prices do not enhance one's ability to predict prices. In the short run, prices are believed by many to follow a "random walk." [See MARKOV CHAINS.] This academic view is at variance with the views of many members of the financial community.

The view that prices follow a random walk is consistent with a market in which numerous pieces of relevant information bearing on future prospects are frequently generated and widely and rapidly disseminated. The pieces of information themselves, however, must be causally unrelated to the historical course of security prices. Another essential condition is that prices adjust "instantaneously" to new information, since gradual adjustment would create trends.

**Organized exchanges.** The most important securities markets in terms of the value of securities traded are organized exchanges. Such exchanges differ from less formal markets in that they centralize communication and trading, impose rules for the admission of persons or firms privileged to trade in securities, impose rules with respect to the securities that can be traded, and closely regulate the procedures used.

By far the largest securities market in the world in terms of the dollar volume of securities traded is the New York Stock Exchange. This exchange, started in 1792 as an informal organization of 24 merchants and auctioneers dealing in securities, has grown throughout most of its history. At the end of 1966 there were 1,366 members of the exchange, most of them associated with approximately 660 organizations, including single proprietorships, partnerships, and corporations. About 1,200 companies with approximately 1,600 different issues of stock were listed, and the more than 10,000 million shares listed had an aggregate value of more than \$495,000 million. In addition, about 500 companies and government agencies with approximately 1,200 different issues of bonds were listed, and these bonds had an aggregate market value of approximately \$120,000 million. At the end of 1966 there were more than 250 listings of foreign securities, including both stocks and bonds,

having an aggregate value of more than \$9,000 million.

The value of securities listed on the New York Stock Exchange at the end of 1966 was more than four times as great as the value of securities listed on the world's second largest exchange, The Stock Exchange (of London), which trades a larger number of issues and has more than twice as many members. The New York Stock Exchange accounts for more than 90 per cent of the dollar volume of trading on the 18 organized exchanges in the United States, and this proportion has been maintained for many years (U.S. Securities and Exchange Commission 1963a).

The number of members of the New York Stock Exchange has been fixed in recent years. Memberships, called "seats," are bought and sold. The price of a seat in 1966 was approximately \$250,000. In 1875 seats sold for as little as \$4,250, and in 1929 they reached an all-time high of \$625,000. To be eligible for membership, persons must meet standards established by the exchange with respect to age, citizenship, character, and knowledge of the securities business.

About one-half of the members of the New York Stock Exchange belong to organizations whose primary purpose is to act as brokers on behalf of those wishing to buy or sell listed securities. These members are paid according to a fixed schedule of brokerage fees averaging roughly one per cent of the value of the security bought or sold, although the fees vary somewhat in a prescribed manner according to the number of shares and the aggregate value of shares or according to whether the securities traded are stocks or bonds.

About one-fourth of the members are "specialists." They are important in the operation of the New York Stock Exchange and other American exchanges, but other devices are used outside the United States, except in Japan, to perform the specialist's function. The specialist receives information from brokers regarding offers to sell and to buy at various prices. Each specialist concentrates his activities in a small group of securities, and brokers wishing to transact business on behalf of the public typically deal with one or another of the specialists handling the stock in question, although brokers may deal directly with other brokers. The specialist secures for the seller the highest available bid and for the bidder the lowest available offer. When there is a wide discrepancy between the highest bid and the lowest offer, the specialist has the responsibility, neither fully enforceable nor precisely defined, to use his own capital to maintain a "reasonably continuous" mar-

ket in such a stock. The specialist is also permitted to buy and sell securities for the account of others, thus acting as a brokers' broker. Regulations of the Securities and Exchange Commission (SEC) require that the specialist must execute orders on behalf of the public prior to executing them for his own account.

Part of the justification given for the existence of the system of specialists is that their trading on their own behalf increases liquidity and reduces the likelihood of large changes in prices between successive transactions. A detailed investigation of the impact of specialists on prices during the period immediately following the assassination of President Kennedy in 1963 revealed that specialists vary widely in their trading practices and in their impact on prices (U.S. Securities and Exchange Commission 1963b). A substantial number of specialists traded so as to diminish volatility, and a substantial number so as to increase it.

Approximately one-fourth of the members of the New York Stock Exchange are either odd-lot dealers or "floor brokers." The former buy and sell blocks of stock of less than 100 shares (odd lots) from brokers representing the public. The latter assist brokers from the commission houses when the volume of business exceeds their capacity to handle it.

Most transactions involve a small enough volume of stock so that the ordinary market mechanism can be used without having a large impact on prices. Transactions, however, which involve very large numbers of shares and dollars are often handled through specialized procedures designed to lessen this impact. The most important type of block distribution is a "secondary distribution" (the sale by an underwriter or group of underwriters of a large volume of stock *not* for the benefit of the corporation whose shares are being sold), but "exchange distributions" (within brokerage houses) and other specialized means of dealing with large volumes of stock are growing in importance. Although the details of these various specialized methods differ, they have in common an effort to accumulate orders to buy from large numbers of investors over a period of time in order to match the large volume of stock that is being offered by a single seller. For instance, in mid-1964, 250,000 shares of a stock selling for \$33 were offered by a single seller. The stock was distributed within one day through the facilities of a single brokerage organization whose customers bought all the stock. The individual purchases were bunched and executed as a package on the floor of the New York Stock Exchange. They were represented as a single

transaction through the national and international communications system that virtually instantaneously transmits information on stock prices. This particular method of distributing stock is known as an "exchange distribution."

The number of shares traded as a percentage of the number of shares listed has been declining secularly. Around 1900, the number of shares traded in a year was approximately 200 per cent of the average number of shares listed in that year, and as recently as 1929 the number of shares traded during a year exceeded the average number listed. Since World War II the number of shares traded in any year has never exceeded 25 per cent of those listed, and in recent years only about 15 per cent of listed shares have been traded in any year.

In order for the shares of a company to achieve initial listing on the New York Stock Exchange, the company must demonstrate earning power, after charges and taxes, of \$1.2 million annually; must have net tangible assets of \$10 million, or more than \$10 million in market value for publicly held shares; and must have at least 600,000 shares publicly held and not fewer than 1,500 owners, each of whom must own at least 100 shares. Similar though less stringent criteria are applied for delisting a stock.

For numerous periods between January 1926 and December 1960 average rates of return to investors investing equal amounts of money in each of the common stocks listed on the New York Stock Exchange were generally higher than earnings in alternative investments, such as government and corporate bonds, savings accounts, and mortgages (Fisher & Lorie 1964). For the entire 35-year period, the average annual rate of return (compounded) to a tax-exempt investor, with reinvestment of dividends, was 9.0 per cent. Without reinvestment of dividends the rate was 6.9 per cent. During the decade of the 1950s, the average annual rates with and without reinvestment were about 15 per cent. (Rates of return with reinvestment may be higher, lower, or the same as without reinvestment. The rate of return is based on the relationship between a change in the value of assets and the volume of assets initially invested. Reinvestment increases both the change in value and the amount invested, and the effect on the rate of return depends on the relative magnitude of these increases.)

Data are also available on the variability of rates of return (Fisher 1965). Considering all possible purchases and sales, at monthly intervals, of all common stocks on the New York Stock Exchange

for the period 1926–1960, it was found that slightly over three-fourths of the transactions were profitable and over half provided rates of return in excess of 9 per cent. Of course, this past experience is not a certain guide to the future.

The Stock Exchange (of London) lists more than 9,000 different securities that had at the end of 1963 a market value of approximately \$125,000 million, about a third of which was represented by debt instruments of the government of Great Britain, Commonwealth governments, local councils, and nationalized industries. The Stock Exchange had about 3,400 members in mid-1964. The relative importance of foreign shares is greater for this stock exchange than for the New York Stock Exchange. The major difference in the method of operation of The Stock Exchange—and almost all exchanges outside the United States—as compared with the New York Stock Exchange is that brokers who buy and sell securities on behalf of the public deal with jobbers who own securities and act as wholesalers. These jobbers, who do not deal directly with the public, serve much the same purpose as the specialist on the New York Stock Exchange, but the specialist in the United States typically has a dual role—broker and dealer—while the jobber in London operates solely as a dealer adding to or depleting his inventory of the securities in which he trades. There are about 280 firms of brokers and about 65 firms of jobbers operating on The Stock Exchange.

A jobber may deal in any listed security, but most specialize in certain groups of shares, or “markets.” The chief markets are as follows: gilt-edged (government issues and other securities grouped with them); banks and insurance; shipping; foreign government bonds; American and Canadian shares; breweries; commercial and industrial; iron, coal, and steel; financial, land, and property; investment trusts; rubber and tea plantations; oil; South African mines; Rhodesian, Canadian, Australian, and miscellaneous mines; West African mines; cables and transportation.

Rates of return on British shares between 1919 and 1963, averaged by 11-year periods, were substantially higher in most of these periods—excluding wartime—than rates on consols—government bonds with no maturity date (Merrett & Sykes 1963). For the entire period, the rates on shares were 8.0 per cent in money terms and 5.8 per cent in real terms, while the comparable rates for consols were 1.4 per cent and –1.4 per cent.

There are other important exchanges in the world, but none approaches in importance either the New York Stock Exchange or The Stock Ex-

change (of London). Among the other leading exchanges are the Stock Exchange of Paris, the Brussels Stock Exchange Commission, the Zurich Stock Exchange (the leading Continental market), the Dusseldorf and Frankfurt stock exchanges in the Federal Republic of Germany, the Milan Stock Exchange, the American Stock Exchange (United States), the Toronto and Montreal exchanges in Canada, and the Melbourne Stock Exchange. There are many regional exchanges in the countries whose leading exchanges are listed above, and there are many exchanges in other countries as well. The largest of these exchanges is not more than about one-fifth the size of The Stock Exchange (of London) or one-twentieth the size of the New York Stock Exchange, and most are much smaller. The mechanisms of these various exchanges differ, but the principles underlying their operation are very much like either The Stock Exchange or the New York Stock Exchange. Information about many of these exchanges can be found in *Spray* (1964).

**Over-the-counter markets.** Unlike the organized exchanges, the over-the-counter market is informal and permits unlimited right of entry by securities and virtually free access of persons into the business of dealing in unlisted securities. At the end of 1963 over 3,300 firms listed with the SEC dealt in unlisted securities. The over-the-counter market differs from the organized exchange in many ways. There is no fixed schedule of fees for buying and selling securities. Dealers more frequently buy and sell from inventories and derive their profit from markups on this inventory.

Dealers and brokers are informally organized in the National Association of Security Dealers (NASD). Under pressure from the SEC, the NASD began to publish in February 1965 wholesale or “inter-dealer” quotations for the 1,300 issues on its national list. Accurate information on retail prices is not yet available for the over-the-counter market.

The SEC estimates that as of December 31, 1962, about 4,500 stocks in about 4,100 domestic companies were quoted only in the over-the-counter market (U.S. Securities and Exchange Commission 1963a). These stocks had an aggregate value of about \$90,000 million, almost half being constituted by stocks in banks and insurance companies. The value of stocks traded over-the-counter was only about one-fourth of those traded on the New York Stock Exchange but far exceeded the value of stocks traded on any other American exchange.

The volume of stock trading over-the-counter is estimated to have grown about eightfold between 1949 and 1961, reaching \$40,000 million in the

latter year. Although most of the very large companies are traded on listed exchanges, this is not true of stocks in banks, insurance companies, and mutual funds, which are frequently large and seldom listed. (In 1964, a Disclosure Act was passed by Congress which may substantially increase the listing of stocks in banks and insurance companies.)

In recent years a so-called third market has increased in importance. This market involves trading in shares listed on exchanges, but the trading takes place in the over-the-counter market rather than through the exchanges. The only definitive estimate of the volume of such trading indicates that in 1961 about \$2,000 million worth of stocks listed on the New York Stock Exchange were traded over-the-counter. This constituted almost 4 per cent of trading on the New York Stock Exchange. This percentage is undoubtedly increasing. The third market is growing in importance because the brokerage costs on the exchanges are fixed and do not permit quantity discounts, despite the lower cost per share of handling large orders. The over-the-counter market has no fixed schedule of fees and thereby permits large buyers and sellers to consummate transactions at lower cost than is possible on the exchanges. The increased importance of institutional investors, who frequently trade in large volumes, has contributed to the growth of the third market.

Outside the United States, most trading in securities is probably through exchanges, but some

**Table 1 — Distribution of total market value of individually held stock, by income class, 1960**

is over-the-counter and through institutions such as commercial banks. In most foreign countries, listing requirements and permission to trade on exchanges are less restrictive than in the United States.

**Share ownership.** In the United States the number of individuals owning stock directly has risen from about 6 million in 1954 to about 20 million in 1966. This ownership is widely distributed among all income groups, as is indicated by Table 1.

Somewhat more is known about the importance of stock ownership by institutions. Such ownership has increased rapidly both absolutely and as a percentage of all stocks, as is indicated by Table 2.

Information regarding share ownership in 60 different countries is contained in a study by the

New York Stock Exchange (1962). Three facts stand out: (1) there is no information about share ownership in most countries; (2) for all countries for which information is available, the number of shareholders is growing rapidly; and (3) share owners constitute a larger portion of the populations of western European countries, Japan, and the United States than of other sections of the world.

In Great Britain, it is estimated by the Wider Share Ownership Council that at the end of 1963 there were about 3.5 million individuals owning stocks directly and that about two-thirds of all adults of the United Kingdom owned stocks indirectly through various institutions. Institutional investors are of greater relative importance in Great Britain than in the United States. British institutions own about 50 per cent of all the securities listed on The Stock Exchange (of London) while the comparable figure for American institutions on the New York Stock Exchange is about 20 per cent. The greater importance of institutions in the United Kingdom is accounted for primarily by the fact that their insurance companies are not so narrowly restricted with respect to the ownership of shares.

Japan had about 4.5 million individual share owners in 1963, over eight times as many as were estimated for 1946.

**The regulation of securities markets.** In the United States, securities markets are regulated to some extent by state laws, but by far the most important regulation stems from the following federal statutes:

- (1) The Securities Act of 1933.
- (2) The Securities Exchange Act of 1934.
- (3) The Public Utility Holding Company Act of 1935.
- (4) The Investment Company Act and the Investment Advisers Act, both of which became effective in 1940.
- (5) The Securities Act of 1964.

(For an extensive bibliography on the first four of these statutes, their amendments, and judicial decisions and administrative rulings derived from them, see Dunton 1963.)

Provisions of the federal statutes are administered by the SEC, which was established in 1934. The Securities Act of 1933 requires the disclosure of financial information judged by the SEC to be relevant for the evaluation by investors of the prospects of corporations issuing new securities. The Securities Exchange Act of 1934 regulates securities markets and the operations of security brokers and dealers. It requires registration of securities exchanges and of securities traded on such ex-

changes; it restricts borrowing by brokers and dealers; it prohibits manipulation of prices of securities; it requires periodic filing of reports on listed securities and the provision of specified information and statements soliciting proxies. Exchanges make rules governing the conduct of their members, and the SEC passes upon the adequacy of such regulation.

The over-the-counter market was brought within the purview of the SEC through a section of the Securities Exchange Act authorizing national associations of security dealers to regulate their members. The NASD, authorized under the Securities Exchange Act, has an extensive set of rules governing the conduct of its members. The Securities Act of 1964 extends to the larger over-the-counter issues the regulations governing registration of securities, financial reporting, and the issuance of proxies that apply to issues listed on exchanges. About 2,000 over-the-counter issues are affected.

The Public Utility Holding Company Act of 1935 was designed to eliminate or control public utility holding companies that either operated in or sold securities in interstate commerce.

The Investment Company Act and the Investment Advisers Act provide for the registration and regulation of investment companies and investment advisers in order to insure a code of conduct and a level of financial responsibility acceptable to the SEC.

Since enactment of the Securities Act of 1933 and the Securities Exchange Act of 1934, the dissemination of financial information by corporations has greatly increased, and the practices of firms buying and selling securities or advising investors have changed significantly. Much of this change has taken place through self-regulation by the organized exchanges and through the NASD.

The impact of these changes and the adequacy of existing regulation were subjected to exhaustive study by a special group established by the SEC, which the Congress had directed to conduct such a study. The study (U.S. Securities and Exchange Commission 1963b) consists of five volumes covering the operation of exchanges and the adequacy of existing regulation, the over-the-counter market, the qualifications of persons in the security industry, security credit, mutual funds, and other matters. A great deal of information, much of it quantitative, is contained in the so-called *Special Study*, but there is controversy as to whether there was an adequate factual basis for the recommendations that were made (Stigler 1964a; 1964b; Friend & Herman 1964; Robbins & Werner 1964).

One major change resulting from the *Special Study* was to subject the over-the-counter market to regulation more like that imposed upon formal exchanges. For the formal exchanges, the major changes, in addition to those resulting from the Securities Act of 1964, were modifications in the regulations concerning floor traders and specialists. The intent of these new regulations was to reduce the advantage of floor traders and specialists relative to the trading public and to decrease possible conflict of interest between their role as speculators and their role of providing liquidity. The new regulations reduce the opportunity of specialists to profit from their access to "book information" about bids and offers, and to execute orders on their own behalf prior to orders on behalf of the public.

**Security credit.** Stocks and bonds are widely used as collateral for loans. At the end of 1964, such loans exceeded \$5,000 million in the United States. This was less than one per cent of the value of all securities listed on the New York Stock Exchange. Loans based upon collateral consisting of securities are subject to special regulation in the United States. The Securities Exchange Act of 1934 required the Board of Governors of the Federal Reserve System to issue rules and regulations concerning security credit, and Regulation T accordingly was issued by them and became effective October 1, 1934. Regulation T specifies the amount of credit that can be extended by security brokers and dealers relative to the value of the collateral. At the end of 1964, such loans were limited to 30 per cent of the value of securities at the time that the loan was made. On May 1, 1936, the Board of Governors of the Federal Reserve System issued Regulation U relating to loans by banks based on collateral in the form of securities. (Extensive information about security credit can be found in Bogen & Kroos 1960.)

**Security prices and business conditions.** Prices of stocks generally move in the same direction as business conditions, rising during periods of expansion and falling during recessions. Prices of common stocks are considered to be a "leading" indicator in that turning points in indexes of these prices typically precede turning points in general business conditions (Moore 1961). The prices of bonds, too, generally move in the same direction as business conditions (Kessel 1965). While stock prices tend to lead general business conditions, movements in bond prices are roughly coincident with movements in business conditions.

Changes in the general price level have different effects upon the prices of stocks according to

the capital structure of the underlying corporation (Kessel 1956). The general principle which explains these variations is that corporations with a large amount of net debt per dollar of equity benefit most from inflation and suffer most from deflation. Net debt is defined as a corporation's monetary assets (cash, government securities, accounts receivable, and notes receivable) minus its liabilities (accounts payable, notes payable, mortgages, preferred stock, and bonds).

The relationship between changes in general business conditions and the prices of stocks is complex because the changes in each series affect each other. Changes in business conditions obviously affect the prosperity of corporations and hence the value of stocks in them. Conversely, changes in prices of stock affect the wealth of individuals and institutions and their willingness and capacity to spend money and to make investments and hence affect general business. From October 1929 to June 1932, the prices of stocks listed on the New York Stock Exchange declined by over 80 per cent, and this reduction of many billions of dollars in the assets of owners of stocks undoubtedly contributed to the great depression of that time.

## SÉE, HENRI

Henri Sée (1864-1936), French economic historian, was born at Saint-Brice (Seine-et-Oise). He attended the Lycée Henri IV in Paris and then the Sorbonne. In 1887 he became *agrégé d'histoire* and taught for several years in the provinces. After successfully defending his doctoral thesis on the policy of Louis XI toward the cities, he was appointed professor at the University of Rennes in 1893. He remained there until a serious illness compelled him to retire prematurely in 1920. He continued to do historical research for the remainder of his life.

The work of Sée has a remarkable unity, which derives from his conception of the aims and the methods of history. His teachers, including Fustel de Coulanges, Ernest Lavisse, and Charles Seignobos, had trained him always to respect the rules of historical criticism. Sée believed that history must be rigorously objective, eschewing, on the one hand, grand systems and philosophies, and on the other hand, the domination of bias. But Sée also realized the futility of a kind of erudition that consists of data increasingly scattered among compartmentalized specialties, no longer useful for the development of synthetic knowledge.

Sée's *Histoire économique de la France* (1939-1942) is the work of a historian who cannot imagine studying economic facts apart from the milieu in which they occur and evolve, and the same spirit prevails in his *L'évolution commerciale et industrielle de la France sous l'ancien régime* (1925a) and his *Esquisse d'une histoire du régime agraire en Europe aux XVIII<sup>e</sup> et XIX<sup>e</sup> siècles* (1921). As a historian who was ever aware of the complexity of the facts, he found the Marxist doctrine of historical materialism unacceptable: from his viewpoint its great defect was its unilateral character. Although he was faithful to the socialist ideal all his life, it was from the effort of human thought rather than from "the blind movement of economic forces" that he expected humanity to progress, and his historical research was designed to show some of the conditions of rational progress.

Like his teacher Fustel de Coulanges, Sée was primarily interested in collective entities and institutions, even though he felt that Fustel had given too short shrift to the actions of individuals and the importance of "accidents." He believed that history should provide knowledge of the institutions, beliefs, and customs of a society, its way of thinking, its dominant concerns, and its guiding ideas. Sée felt that the most certain way of making his contribution to history as the "science of human societies" was to devote himself to both social and economic history and the history of ideas. Neither political or military history nor the biographies of rulers serve to reveal peoples to themselves. The most important dynamic factors in the evolution of societies are economic necessities, which predominantly determine the feelings and actions of governments and of social classes; however, the economic factor does not explain everything, and economic interpretations of history by no means have the character of laws.

Sée was a prolific author, his writings comprising no less than 28 books and 194 articles. As economics editor of the *Revue historique* he performed an important service to his profession.

## SEGREGATION

Segregation is an institutionalized form of social distance expressed in physical separation. It signifies a convergence of physical and social space and is to be distinguished from other social forms which also structure social distance in spatial terms, as, for example, the elaborate patterns of deference in African societies with sacred kingship or the different levels of seating (reflecting caste status) among Singhalese castes. The latter regulate social relationships between persons in situations of contact; segregation refers primarily to the separation of persons and the avoidance of contact.

Systems of segregation vary in the *criteria* which distinguish the segregated groups, whether biological, cultural, and/or status, and in the situations, or roles, which are segregated. Segregated roles may vary in extensiveness (extreme separation being represented by indirect rule in colonial society), in type (the intimate roles of primary relationships or the more impersonal roles in secondary relationships), and in the relative level of the actors (for example, where equal-status contacts are proscribed but dominant-subordinate contacts are fostered, as in racial segregation, or apartheid, in South Africa). Segregative systems may also be distinguished as compulsory or voluntary, as deliberate or spontaneous, and as influenced posi-

tively by attraction or negatively by disdain. Compulsory segregation involves deliberation and invidious distinction and serves the interests of those who impose it.

Although segregation imposes separation of persons and groups, it is by no means the antithesis of societal integration. The segregation of units may be a basis for integration, as in traditional Indian caste society, where a consensual basis for segregation was derived partly from shared religious values. Indeed, segregation may be conceived of as a general, although not a universal, aspect of social organization. It defines the boundaries between groups, locates the groups in the hierarchy, and regulates their interaction. Because of the intimate relationship of segregation to systems of domination, it is often highly resistant to change and readily becomes a focus of political conflict.

**Sociological approaches.** Early sociological concern with segregation derived in part from interest in the processes of social interaction (segregation being conceived of as "dissociative," in terms of a model of "attraction-repulsion" or "association-dissociation") but mainly from ecological studies, under the influence of animal and plant ecologists, geographers, and the theory of social Darwinism. The initial emphasis on the biotic approach stressed the subsocial elements in human society, with the corollary, explicit or implied, that segregation was a natural phenomenon; there was the same implication in the concept of natural areas [see REGION].

By contrast, the cultural approach, which developed in criticism of the biotic, stresses the influence of *values* on the spatial distribution of urban populations, especially the role of prejudice and discrimination in the segregation of ethnic and racial groups. Sociologists share with social psychologists and political scientists an interest in the psychological consequences of segregation as it affects the processes of prejudice, consensus, and political cleavage. And this interest has been further stimulated by the struggle for desegregation in the United States—a major focus of the movement to secure effective civil rights for Negroes—and by the threat of racial civil war in South Africa, which has a regime of systematic racial and ethnic segregation.

**Social structural factors**

Segregation, being an aspect of social structure, varies in its incidence and nature with the type of society. It hardly exists in relatively undifferentiated societies, such as those of the Bushmen, and the term is not really applicable to the divisions

between kin groups in segmented societies, which constitute separate rather than segregated units, loosely federated in certain situations.

**Social differentiation.** While segregation is associated with social differentiation, there does not appear to be a precise relationship between the two. Segregation may be highly elaborated both in societies where the division of labor is not greatly advanced and in modern industrialized societies. Thus, segregation is a basic principle of organization in the village communities of Indian caste society, where it regulates residence, access to amenities, and contact between the castes and where it receives ritual reinforcement in patterns of avoidance sanctioned by the threat of pollution. It is found in many "preindustrial" cities in Europe, Asia, and the Middle East and in the Muslim cities of north Africa, where ethnic and religious particularism may be manifested in separate quarters of the city as well as in occupational specialization. And it is characteristic of the most industrialized metropolitan cities of North America, in which there is extensive segregation of Negroes in residence, worship, education, and social intercourse. Nor does it seem that progressive industrialization will necessarily dissolve ethnic and religious particularisms that are irrelevant to the industrial process and replace them by distinctions resting on more universal criteria of qualification and achievement. This may be the trend within industry, but there is a continuing relevance of ethnic and religious identification as bases of association in the cities and in the extensive movement of urban populations to the suburbs.

**Social stratification.** The relationship between segregation and rigidity of social structure is equally complex. Segregation is characteristic of societies with complex class systems, although the ecological patterns of class segregation vary and a central city location may distinguish the upper classes in one society, the lower classes in another. There may be extensive segregation of roles in a class system, where residential segregation lays the foundations for segregation in education, religion, and recreation. But the barriers are much more permeable than in caste systems; in fact, in these two systems there is a direct relationship between the rigidity of the system of stratification and the rigidity of the system of segregation. This relationship, however, does not hold for the slave plantations, in which the extreme of social distance was nevertheless compatible with intimate contact. Segregation is one of many forms of institutionalized social distance and not in itself a precise indicator of social structure.

**Pluralism.** Plural societies have an affinity for segregation, especially when the social cleavages between racial, ethnic, or tribal groups are associated with cultural differences, as in the colonial societies of Africa. The policies of the metropolitan powers imply different policies toward segregation. In theory, Africans who acquire Portuguese or French culture may move freely in the circles of the conquerors, acculturation bridging the social cleavages between them. The British theory of indirect rule, by contrast, maintains the separation between the races by a system of parallel institutions, which extends to the courts of law; legal and other dualisms help maintain cultural diversity, and acculturation does not qualify individual Africans to cross the barriers of segregation and racial cleavage. In South Africa, a system of parallel institutions and consequent segregation serve to foster nationalism among the Afrikaans-speaking white population and to segregate racial, ethnic, and tribal groups under the policy of apartheid.

#### Patterns of racial and ethnic segregation

Different historical circumstances influence the patterns of segregation between the races. For example, after the conquest of Algiers the French settled inside the depopulated city, whereas in the protectorate of Morocco, which was constituted by treaty with the sultan, they established separate cities adjacent to the Muslim cities (Le Tourneau 1957, pp. 112-113). Segregation is also affected by the extent and nature of administrative regulation. In British and French west Africa, racial segregation was social and customary; in the Belgian Congo and southern Africa, it was legally imposed and sanctioned. In South Africa it is systematized under town plans, which tend to reserve the core of the towns for whites and to move nonwhites to the periphery or beyond or to establish them in satellite towns.

**Colonial Africa.** Whatever the colonial policy, the historical conditions, or the administrative framework, the general pattern in colonial Africa is one of racial segregation, and in east Africa and South Africa it extends also to intermediate groups such as Indians. The generality of racial segregation in colonial Africa flows from the convergence of many different types of social distance, based on race, power, class, and culture. Inevitably, the lower classes on the fringes of urban life (the so-called *sous-proletariat*) who live in the improvised shanty towns, or *bidonvilles*, are recruited from the population of the colonized, and the residents of upper-class neighborhoods are the colonizers. Cul-

tural differences extend racial separation to many institutional spheres. Even in shared institutions (as in the conversion to Christianity), ideologies of domination or sentiments of superiority fuse with cultural and racial differences to create varied and intricate patterns of integration and segregation, including, in extreme cases, reinterpretation of the communion with Christ.

*Tribal segregation.* Tribal segregation in colonial society is less general and more varied in its forms. In the old cities of Africa, uncontrolled residential patterns permitted tribal concentrations. In the new cities, housing policy, control over the influx of migrants, and the demand for housing all affected the possibility of tribal segregation. In some areas it was discouraged by indifference to tribal affiliation in the allocation of housing; in others, though less often, it was the principle which governed the allocation. Sometimes housing policy and social conditions were sufficiently flexible to permit a measure of voluntary tribal segregation. The relations between tribal hinterland and city, tribal composition and relative concentration or dominance of different tribes, extent and organization of industry, and political structure all have a bearing on the incidence of tribal segregation. Cultural differences encourage the spread of tribal segregation into a variety of institutions, as shown for example in the establishment of separate mosques by many tribal groups in Freetown, Sierra Leone (Banton 1957, p. 137). In general, the acquisition by different tribesmen of elements of a common culture in the urban setting and through the schools, as well as their common subordination to the colonial power and the processes of restratification, reduce the relevance of tribal affiliation and provide new bases of association.

African independence may have different consequences for racial and tribal segregation. In the case of racial segregation, the policy of Africanization is designed to effect desegregation, at any rate in the more public spheres of life, indeed, it may carry the process to the point of an African imposition of exclusiveness. In the case of tribal segregation, there is the bond of common race to bring tribesmen together, and the cultural differences between the tribes are more readily bridged than those between the races. But under some conditions of social structure, that is, where organization of the tribal unit offers access to power, the political struggle after independence may give enhanced significance to tribal affiliation and association.

*United States.* Segregation in the United States has rested on such varied aspects of pluralism as

race, ethnic background, religion, and culture, or combinations of these, in association with class differences. It is most resistant to change in the case of Negroes. Cultural differences between Negroes and native-born white Americans are not marked. The basis of segregation is the general interaction of lower-class status and invidiously defined racial status. Differences in racial status are institutionalized in the structure and culture of the society, although ambiguously, since this conflicts with the democratic ethos. Persons of low racial status have little access to opportunity for achievement, because of segregation in poor neighborhoods and inferior schools and concentration in manual and unskilled occupations. Conversely, the relatively lower levels of achievement reinforce the depreciation of the Negro's racial status.

The mechanisms of this racial segregation vary. In the South, the enactment of laws to enforce segregation was encouraged by the decision of the U.S. Supreme Court in *Plessy v. Ferguson* (163 U.S. 537, 1896), which held that the provision of separate but equal facilities was not a violation of the right to equal protection of the law under the fourteenth amendment to the constitution. But compulsory segregation did not include racial zoning (in contrast to South Africa), since the Supreme Court refused to accept the doctrine of "separate but equal" as legitimizing residential segregation. In the North, convention, restrictive covenants, discriminatory housing policies, poor wages, and the continued movement of new migrants into low rental areas of established Negro settlement all contributed to a high level of residential segregation, which provided the core for extensive institutional segregation in education, religion, and politics. With the removal of many of the legal supports of racial segregation, pursuant to decisions of the Supreme Court, and despite the official policies of the federal government and a number of states and cities, segregation is still carried forward by various deliberate means, such as the controls applied by boards of realtors, as well as by its own momentum and the consequences of past segregation. Since Negroes were largely excluded from the movement to the suburbs, the central core cities in the great metropolitan areas become increasingly nonwhite as the racially segregated urban populations receive the new Negro and other colored migrants.

*Ethnic groups.* The patterns of ethnic segregation in the United States are similar to those of racial segregation. Foreign migrants establish themselves in central city areas, in zones of transition, and in the interstices of the city, where they

create "Little Sicilies" or Jewish ghettos or other incapsulated communities, which are often characterized by poverty and social disorganization. In this respect they are very similar to the racially segregated communities; however, the ethnic groups and their settlements dissolve more readily in the environing society under the conditions of immense growth and vastly expanding opportunities experienced in the United States. Cultural differences diminish as the political and economic institutions, the schools, and mass media powerfully shape a common culture. With the passing of time, ethnic background tends to become detached from social class and culture. It still remains relevant for association or exclusion, and ethnic enclaves persist and are transported to new suburbs. But ethnic segregation becomes less general than racial segregation, less discriminatory, and less extensive in the range of roles affected (being emphasized more in primary than secondary relationships). Some ethnic identities have merged into an upper stratum of Anglo-Saxon and north European American identity. Religious identity—that of Protestant, Roman Catholic, and Jew—subsumes in some respects the ethnic identity, replacing its exclusive particularism with a more general principle of association.

**Comparison of racial and cultural criteria.** Comparison of Negro and Puerto Rican segregation in New York City, as it develops over the years, may provide some measure of the relative emphasis on racial and ethnic background in the integration of groups into North American society; however, interpretation is rendered difficult by an admixture of color in the Puerto Rican migration, and by the very different significance, history, and organization of the two groups in the wider society. Probably the situation of Negroes in the United States is unique, and their former slave status may be as relevant as their racial origin.

In England, there are appreciable numbers of colored people who entered the country after World War II; although they constitute little more than 1 per cent of the population, their presence has created an awareness of a color problem. Since they are of varied cultural background (mainly from India, Pakistan, and the West Indies), comparative analysis may yield some insight into both the role of race and of cultural differences in the exclusion and segregation of minority groups in England. If English prejudice against people of other races is only an expression of a more general xenophobia, and not specifically racial prejudice, as some English sociologists maintain, then it follows that cultural difference should be the crucial

variable in the exclusion of strangers. The evidence indicates some residential concentration of immigrant groups, whether colored or not, in different boroughs of London, and some dense clusters of colored groups, but also much dispersion. There is exclusion of colored people in primary relationships, much discrimination in rented accommodations, and some discrimination in employment (Glass 1960; Davison 1963; Deakin 1964). But citizenship rights may be fully exercised, regardless of race, and such public amenities as transport are not segregated.

The relations between race, culture, and segregation are, no doubt, indeterminate; they vary in different social contexts and historical situations. Segregation is by no means a universal corollary of racial differentiation. Racial difference may be relevant for social stratification, but expressed little, or not at all, in segregation; or its relevance may be indirect, that is, resting on association with class and cultural differences (the seemingly biological description of groups referring to sociocultural distinctions, as in Mexico); or the reality of racial difference may be submerged in a social myth of racial homogeneity, as in Argentina (Beals 1955; Taeuber & Taeuber 1965; Schnore & Evenson 1966).

Since racial segregation rests on relatively enduring characteristics, it is likely to be highly persistent, once it becomes established and linked with structures of domination. But even this is not certain. Residential and other forms of segregation by race may rapidly disappear with sharp changes in the structure of power, as is to be anticipated in the independent states of Africa.

### Ideological bases of segregation

After World War II, movements for racial desegregation were stimulated both by changes in the internal structure of the societies in which they arose and by the changed relationship between white and nonwhite peoples in the world structure of power. The emancipation of colonial peoples is essentially an emancipation of nonwhites from white domination. Concerned with eliminating the racial discrimination they suffer in their own countries, they are affronted by its practice in other countries. Since the distribution of races crosses national boundaries, movements for racial desegregation acquire international significance. It becomes increasingly difficult to justify racial segregation as *ideologies* of segregation are undermined by a world ethos of universal human rights.

**Religious doctrines.** Ideologies of segregation form around major social values. They may be

expressed in religious terms. Thus the concept of *pollution* regulates contact and avoidance in a most extensive range of roles by supernatural sanctions and by sentiments of deep revulsion for defiling contacts. Doctrines of *predestination* afford justification for controlling level of contact and for discriminating against persons who are not members of the elect; they may also serve for an extensive regulation of roles.

Resentment of invidious status under theories of predestination may provoke countertheories which emphasize reversal of status. In some of the African Zionist and messianic movements, it is the black prophet who seeks a "New Jerusalem" on earth for the chosen African people or closes the gates of heaven against the white man. In the racially exclusive religious movement known as the Nation of Islam, American Negroes may find eschatological vindication of their race and a rationale in divine destiny for a policy of territorial separation (Lincoln 1961).

Doctrines of racial predestination are not easily maintained in Christian churches, where they are almost universally disavowed. They may reappear, however, in doctrines which enjoin separation, although they abandon the invidious racial distinctions in deference to the world ethos of human equality. In one variant, the existence of separate races is taken as evidence of "divine providence" and of a religious duty to preserve racial separation by avoidance of contacts which might lead to the intermingling of races and loss of racial purity.

**Natural instinct theory of segregation.** Scientific ideologies rest on assumptions as to the nature of man and of human society. The assumed ubiquity of racial segregation is often taken as evidence that it derives from the instinctive nature of man. There are similar implications, though without racial connotation, in the concept of the fight for "turf" as the human counterpart of the animal instinct for "territory." A natural instinct theory of racial segregation may serve as an ideology for compulsory segregation, which is thus conceived as consonant with the true nature of man; or it may serve as a defense against compulsory segregation, since the natural proclivity of races to segregate themselves would render compulsion redundant.

**Measurement of segregation.** The prevalence of racial segregation cannot be doubted, although there is little precise information as to its extent. Segregation may be measured statistically by an index of dissimilarity in the spatial distribution of two groups, or by indexes of segregation, which calculate either the difference between the distri-

bution of one group and all other groups or the deviation from a postulated norm of even distribution. Moreover, an index of segregation may be combined with other measures, such as social rank and urbanization, to yield an urban typology, as in "social area analysis" (Shevsky & Bell 1955).

There are difficulties in the use of these measures of segregation. They are relative to the system of area units used, whether blocks or census tracts; they leave out of account the presence of segregated clusters within units, since they are based on the assumed homogeneity of these units; they may be affected by the relative proportion of the segregated group in the total population; and they measure the results of a complex of factors, not only the influence of the racial factor in segregation (Duncan & Duncan 1955, pp. 215-217). Furthermore, they impose the need for surveys to collect the basic data in countries which do not take a census of their populations or do not inquire into racial identity. But they do provide a basis for comparing racial segregation in different societies and for estimating its extent. In the absence of reliable comparative data from countries other than the United States, in which these measures have been widely used, assertions as to the generality and extent of racial segregation rest on impression.

**Other forms of ideological defense.** Other forms of scientific ideology postulate the inevitability of conflict in the contact between peoples of different culture or race and hence the necessity for avoiding contact. Or they assert as a corollary of the natural instinct theory of segregation, that racially mixed areas are inherently unstable and tend to revert to the segregated state. In this conception, when members of a subordinate race "invade" the residential area of the dominant race, the residential cycle ends in a racially segregated area for the invading group, since the original residents evacuate their homes; thus invasion becomes succession. In capitalist society, the protection of property rights and values may provide an ideological defense against desegregation. Prohibition of racial segregation in the leasing or selling of property may be represented as an infringement or diminution of rights of ownership and desegregation as a threat to property values under an assumption of inevitable depreciation.

Refutation of the theoretical assumptions in these ideologies involves the demonstration of contrary cases of stable racial intermingling, of contact without conflict, and of the maintenance, and indeed enhancement, of property values. This type of analysis rejects categorical assumptions as to

the nature of man and society and focuses on the conditions which give rise to racial segregation or those which favor the intermingling of races or promote desegregation.

# Segregation and prejudice

Desegregation may be effected by revolutionary changes in the structure of the society, as in many parts of Africa, or it may be sought within the existing structure by action against prejudice and discrimination. Segregation is not necessarily associated with prejudice, since it may be maintained by the institutions of society, independently of the attitudes of individuals. But in general, systems of segregation draw support from the prejudices of individuals and indeed foster those prejudices. In situations of systematic racial segregation which permit contact only on a basis of inequality, the routine experience of racial superiority may be expected to intensify sentiments of superiority and sentiments supportive of segregation; these sentiments in turn seek expression in further segregation, so that the levels of both prejudice and segregation are raised by their mutual interaction. Conversely, under certain conditions the experience of contact on a basis of equality may undermine prejudice and weaken the support for segregation. Studies of interracial housing projects in the United States have shown the influence of residential proximity, official policy, and perceived social climate in creating more favorable attitudes (Deutsch & Collins 1951; Wilner et al. 1955). Action programs to promote racial harmony and equality may emphasize desegregation, since racial segregation is mostly overt and public and hence amenable to control by legislation and administrative regulation and since attitudes may be modified by changing the context and experience of race relations.

## SELF CONCEPT

Historically, the domain of investigation subsumed under "self concept" by psychologists and sociologists was a major concern of theologians, philosophers, political essayists, playwrights, and novelists. Since differences in defining the domain exist even today, it is hazardous to start with a definition without first preparing ground on which terms of the definition can be built. This task is undertaken here through a glance at the status of the self concept in contemporary psychology and through a brief report of representative conceptions by various writers, noting convergences and differences. With an adequate definition, developmental and experimental research can be reviewed to derive leads for a conception of self that is scientifically based, rather than one that suggests "my word against your word."

### Current status and historical background

Especially since the 1940s, problems related to self concept have surged forth as indispensable

and legitimate topics for scientific study in psychology and sociology. The interest in self can be appreciated better if we consider the years of its relative disuse, and even disrepute, in the mainstream of psychology between 1900 and 1940. These years correspond roughly to the period of dominant concern with asserting the scientific nature of psychology by shying away from any concepts associated with the philosophical origins of psychology. The brave new world of scientism was represented by the models of Wundt and Titchener and by the behaviorism of Watson. The first asserted that the prime task of scientific psychology was the discovery of mental elements and then the laws of their compounding; the second, that the scientific task was a search for elemental reflexes and principles of their linkages. Each model, in its own terminology, advocated its approach as the only way to lay solid foundations for the ultimate explanation of more complicated forms of behavior.

Even then, the picture was not entirely monolithic. There were always those in search of unifying, integrating concepts to handle problems of the consistency of the person and the continuity of this consistency over time. The memorable chapter on self by William James (1890) maintained its impact on psychology and social science even during the period in question. James analyzed the self in terms of its constituent parts, as the sum total of what the individual considers himself and his to possess, including his body, his traits, characteristics, abilities, aspirations, family, work, possessions, friends, and other social affiliations. James neatly boiled down the problem of the maintenance of self-esteem into a formula (Self-esteem = Success/Pretensions) that served as the basis of many formulations and much research by psychologists and sociologists. Among his other insights, James anticipated the core of modern formulations on reference groups. He wrote of the individual's "image in the eyes of his own 'set,' which exalts or condemns him as he conforms or not to certain requirements that may not be made of one in another walk of life" [1890, vol. 1, pp. 294-295, see also the biography of JAMES].

Among other influential contributors was James Mark Baldwin, who gave an interactionist account of self development, epitomized in his formulation: "The ego and the alter are . . . born together" ([1895] 1906, p. 338). Some years later, the development of self through social interaction was elaborated by the sociologists Charles H. Cooley (1902) and George Herbert Mead [1913; see also INTERACTION and the biographies of BALDWIN; COOLEY; MEAD].

Of course, even in the first half of the twentieth century, there were the "personalistic" psychologists, such as Mary W. Calkins and Wilhelm Stern, who insisted that self-reference was characteristic of all psychological activity. Such formulations would find an ardent advocate later in Prescott Lecky's *Self-consistency* (1945). But the experimental mainstream was a psychology that had banished the self and other integrative concepts. [Cf. Allport 1943; see also PERSONALITY: CONTEMPORARY VIEWPOINTS, *article on A UNIQUE AND OPEN SYSTEM*; and the biography of STERN.] As a result, it never came to grips effectively with problems of human motivation (e.g., Koch 1956) nor with regularities in human behavior on the conceptual level of functioning (Schneirla 1946; 1951). Research results were fragmentary and attempts to put the fragments together proved inconclusive and even contradictory, showing little resemblance to the characteristic consistency of the person as he pursues the satisfaction of his needs for food, sleep, and sex and as he works and plays with his fellows.

As a rule, the person searching for food is not guided by hunger alone; he is also guided by what he considers to be proper food, the place where it is located, and the atmosphere where it is eaten. The tired traveler looking for a hotel is not merely concerned that the bed be like his own bed at home or perhaps a bit more comfortable. He is equally, if not more, concerned with the class of the hotel, whether it is on a par with his standing in life, and how his friends, employer, or sweetheart will react when he announces where he is staying. Ordinarily, the search for a sex partner is not guided merely by the urge for any sex object immediately available, who will serve to reduce tension and restore the homeostatic level. The episodes of sexual activity, beginning with the search, are also guided by proving one's worth and status as a man or woman both to oneself and to others.

Therefore, the individual's self is involved in more than striving to raise one's prestige, status, or self-esteem. Typically, self becomes involved in the operation of motivational urges, whether the individual is aware of it or not. The pervasive presence of self factors is expressed well by Shoben: "In any case, self-involved behavior seems close to impossible to explain on the basis of a tension-reduction model, and the postulation of self-involvement seems necessary to account for the pursuit of long range goals so typical of human motivation" (1962, p. 771). [See MOTIVATION, *article on HUMAN MOTIVATION*.]

The regulation of behavior by self is not restricted to motivational activity. Self concerns

enter as regulating factors into many psychological processes: judging, perceiving, learning, remembering, thinking, planning, and decision making. In performing a task, level of performance is not determined solely by the nature of the problem (difficulty or ease, for example). The goals one has erected for oneself in general, the place of the particular task in one's scheme of goals, and one's standing relative to others on the task all enter the picture and affect one's performance. During his development, the individual comes to stand in established reciprocities with others, as high, low, or equal; friendly or unfriendly; dominant or subordinate. When stabilized, these reciprocities form patterns producing regularity and consistency in the individual's dealings with others.

In series of encounters with others, the individual develops self-identity, in various respects, which is reflected in consistency in his dealings with others and with situations from day to day. In different situations, relevant components of the self are aroused, lending to his behavior characteristic modes of reacting to, and coping with, situations.

In brief, the growing interest in a self concept reflects the search for integrative concepts, particularly in motivation, where empirical work has tended to be fragmentary. Studying motives separately has fallen short in providing an adequate account of human motivation. The self enters into the operation of human motives as a regulative factor. So, too, self enters into other psychological processes. Involvement of the self in these processes is reflected in the consistency of the person and its continuity from day to day. In fact, self involvement in particular aspects of the kaleidoscopic stimulus world is the basis for the experience of continuity in personal identity.

### Usages of self concept

For reasons mentioned, problems of self or ego came irrevocably to the foreground as a legitimate area of investigation. Yet exactly what the concept covers, its relation to other integrative concepts (e.g., role, ego, personality) are still not crystallized. A convenient summary of different usages is presented in Hall and Lindzey (1957, pp. 467-499).

Not including the primarily psychiatric and clinical conceptions in our consideration, a major definitional divergence is represented between those who differentiate between the concept of self and the concept of ego and those who use the concepts of self and ego interchangeably. Ausubel (1952), Chein (1944), Hilgard (1949), Murphy (1947), and Symonds (1951) are among those

Figure 1

Source: Adapted from Ausubel, David P., *Ego Development and the Personality Disorders*, 1952, Grune & Stratton, Inc. Reproduced by permission.

who propose to use the concepts of self and ego in a differentiated way. Allport (1943), Snygg and Combs (1949), M. Sherif and Cantril (1947) are among those who use the words self and ego interchangeably.

**Self differentiated from ego.** An account of all the possible variations in differentiating the ego concept from the self concept is not within the scope of this article. It will suffice to examine representative ways in which they are differentiated. Murphy's definitions of self and ego in his monumental *Personality* (1947) provide one example: "Self: The individual as known to the individual" (p. 996); and "Ego: Group of activities concerned with enhancement and defense of the self" (p. 984). Here, "self" is used to mean the object consisting of so many attitudes and feelings in regard to the person himself, and "ego" is used to refer to the representative processes or activities.

Ausubel offers still another example. His diagram of the relationship of self, ego, and personality (Figure 1) clarifies his differentiation (1952, p. 13).

It may be fair to summarize Ausubel's schema by saying that the self is made up primarily of perceptual components, and ego consists of these and affectively charged conceptual components (self-ideals, self-values, etc.). But a clean separation between perceptual and conceptual components does not seem to fit into the ongoing developmental picture. As the child acquires labels and categories of language, "the self becomes less and less a pure perceptual object, and more and more a conceptual trait system" (Murphy 1947, p. 506).

Once the child starts acquiring language the body image becomes increasingly invested with value attributions that vary from culture to culture and from class to class (e.g., modesty in exposure, cleanliness, desirable body proportions, proper items to cover and adorn the body). Likewise, in building a self-picture the place of one's name is not restricted to auditory images: as McDougall noted, it soon becomes a handle to which many attributes are tied. Anthropologists have reported

cases in which personal names are changed at important transitions in people's lives. For example, A. R. Radcliffe-Brown (1922, p. 119) reported the change of name of Andamanese girls at the time of first menstruation. Likewise, Rivers reported the case of a Melanesian culture in which "on marriage both man and woman change their names and assume a common name" (1914, p. 347).

**Self interchangeable with ego.** Some authors seem to use either the concept of ego or the concept of self to cover a broad range. For example, Shoben defines "self" as "a relatively stable organization of values that mediates and focuses behavior" (1962, p. 771). George A. Miller defines "ego" as "the individual's conception of himself" (1962, p. 347). In view of this terminological malaise, it might be preferable to discard the labels "self" and "ego," fraught as they are with historical entanglements, and to use new terms not so encumbered. The new term proposed by Allport to replace the self and ego concepts is "proprium" (1961, p. 127). However, contemporary social psychologists, concerned as they are with the development of the personal identity of the individual—its enhancement and defense in social relations—seem to get along in their conceptualization without being concerned over the terminological differentiation between ego and self (Krech, Crutchfield, & Ballachey 1962; Newcomb, Turner, & Converse 1965; Secord & Backman 1964; Sherif & Sherif 1956).

### A characterization of self concept

On the basis of the foregoing considerations and surveys of theoretical and empirical literature, several propositions seem warranted.

Self (or ego) is not innate, as are the individual's organic urges—such as hunger and sex—which are subject to homeostatic regulation of the organism. Self (ego) is the product of interaction, from infancy onward, with the individual's physical and social environment. This interaction is associated with novel and familiar sensations: pain, resistance, acceptance, rejection, and gratification. The proposition that self is a developmental forma-

tion is one of the most widely documented generalizations among investigators from the nineteenth century on, despite variations in the specifics of their accounts.

There is also agreement that this psychological formation of the human individual is not a unitary structure, appearing full-blown. It develops first as a perceptual system based on the differentiation of one's body and its parts from its surroundings. It becomes progressively a more complex conceptual system, consisting of evaluative categories with associated traits or attributes. New classifications and qualities (e.g., adolescence, old age, acquisition of new interpersonal roles and social status) continue to be incorporated in the system during the life span (cf. Murphy 1947, pp. 489 ff.; Snygg & Combs 1949, pp. 78-79).

To emphasize the multifaceted character of the person's identity, William James (1890) analyzed this uniquely human formation in terms of the person's "selves." However, various components of the self formation are interrelated; different components may be mutually supportive or conflicting, depending on the situation. To underscore both the multifaceted nature and interrelated nature of self components, it is preferable to use a generic concept (self) subsuming the components, referring to the latter by terms other than the various "selves."

Therefore, the components are referred to as attitudes or self-attitudes, to specify that they pertain to relatedness of self to objects and persons important to the individual. Here, the term "attitude" is used to refer to more or less lasting evaluative categories of the person. (More transitory internal states may be referred to by other terms, such as "set," "expectation," or "bodily urge.") The definition of "attitude" here is similar to that given by Smith, Bruner, and White: "We define an attitude as a predisposition to experience a class of objects in certain ways, with characteristic affect; to be motivated by this class of objects in characteristic ways; and to act with respect to these objects in a characteristic fashion" (1956, p. 33). [See ATTITUDES.]

Combining these fundamental points, the characterization of self (ego) is as follows: Self is a developmental formation in the psychological makeup of the individual, consisting of interrelated attitudes that the individual has acquired in relation to his own body and its parts, to his capacities, and to objects, persons, family, groups, social values, goals, and institutions, which define and regulate his relatedness to them in concrete situations and activities.

The attitudes that compose the self system are, therefore, the individual's cherished commitments, stands on particular issues, acceptances, rejections, reciprocal expectations (roles) in interpersonal and group relations, identifications with persons or values, and personal goals for the future. When any of these—singly or in varying combination—enter as factors in ongoing psychological activity, owing to their relevance, behavior acquires characteristic directionality (positive or negative), becomes more consistent and selective, and is less bound by the ups and downs of the immediate situation. Ego involvement simply means involvement of such an attitude in ongoing psychological activity. Ego-involved activity is characterized by highly sensitized mobilization of the individual's psychological processes (discrimination, perception, learning, remembering, problem solving, decision making, and so on). Ego-involved activity, revealing aspects of an individual's personal identity, has been demonstrated empirically in many studies since the 1940s. (Note again the terminologically unhappy fact that these studies are almost always presented as studies of ego involvement, not self involvement.)

Defining, as they do, the individual's identity relative to objects, persons, groups, and situations around him, these self-attitudes determine the individual's experience as an active agent, principal actor, or executor when they participate in ongoing psychological activity. Therefore, it is not parsimonious to posit separate psychological concepts to account for experience of the person as executor and doer (cf. Ausubel 1952, pp. 41-46).

Thus, the unique formation that takes shape as the self or ego of the human person consists of a set of components that define his stabilized bearings in relation to the physical and social surroundings. They define his ties, his reciprocal expectations of his rights and responsibilities, and his motivational-emotional claims relative to objects as well as other persons, groups, and institutions. They define his stands and commitments relative to the social issues that are important to him. All of these components of the individual's self set him apart as a person in diverse ways and capacities with a sense of unique self-identity.

The stability of the person's self-identity is, therefore, dependent on the stability of the ties, roles, commitments, and orientations that compose it. They provide anchorages relative to which he gauges his personally felt status, security, and prestige, and his maintenance or gain in position in the social scheme of which he is a part. His experience of success or failure arises relative to

them. Hence, maintenance and continuity of the stability of these anchorages from day to day become matters of utmost importance in the dynamics of his motivational scheme.

Disruption of the stable anchorages that define the person's bearings relative to his surroundings arouses tensions, referred to as the state of uncertainty or anxiety, that are distressing or even unbearable. Experimental evidence shows that the loss of stable anchorages in the person's surroundings arouses feelings of uncertainty and insecurity, causing him to flounder about in efforts to restore his sense of personal stability. The experience of loss of his bearings makes an individual more susceptible to conforming to social influences to which he would ordinarily pay less heed (M. Sherif & Harvey 1952).

Similarly, disruption of stabilized personal ties, loss of acceptance by groups that he values, or lack of stable ties with others generate intense feelings of aloneness and personal rejection. Communications that advocate points of view divergent from the strong commitments incorporated in the self system arouse dismay, irritation, and tension. The committed person finds such communication more divergent from his stand, more unreasonable, and more obnoxious than does a person who is less committed. Thus, self-attitudes are resistant to communication designed to change them.

### Formation of self (ego)

Based on extensive surveys of research on child development (M. Sherif & Cantril 1947; Murphy 1947), this account notes a sequence of major events marking ego formation. Differences in age of occurrence and forms are to be expected in differing cultural and socioeconomic conditions.

Neither early observations of individual children nor modern studies of groups of infants provide evidence for innate self-identity. The infant's behavior is readily attributable to bodily states (hunger or sleep, for example) or the duration of immediate environmental stimulation. In fact, consistent differentiation and localization of the body parts require repeated experiences in localizing stimulation, meeting obstacles arousing unpleasant sensations, and exploring both body parts and environment. The earliest manifestations of self-awareness appear during this "perceptual stage" (Murphy 1947), in which the body is perceived apart from the surroundings. [See INFANCY, *article on* INFANT DEVELOPMENT; SENSORY AND MOTOR DEVELOPMENT.]

Cases of prolonged isolation in childhood suggest that ego formation beyond the stage of a per-

ceived body depends upon interaction with other persons who are members of a social and linguistic community (cf. Lindesmith & Strauss 1949). This accords with early theoretical accounts and modern formulations based on research conceiving of self as a product of interaction with others (e.g., Wallon 1934; Piaget 1932).

Facilitations and resistances, acceptances and punishments by persons who care for the child are landmarks for the developing self. Through such interactions, the child begins to acquire spoken language, at first slowly, then at a rapidly accelerating pace (during the second or third year of life). The acquisition of language is the single event most responsible for producing the consistency in behavior that requires postulation of a self system. [See LANGUAGE, *article on* LANGUAGE DEVELOPMENT.]

When the child is able to designate self and others through personal pronouns, a name, or verb forms, even the bodily self is delineated more sharply from its surroundings. Henceforth, the body itself is classified and endowed with attributes (favorable or unfavorable) through interaction on a verbal level. The striking variations in boundaries and properties of body image found in persons of different sex, age, culture, and states of bodily injury led Fisher and Cleveland (1958, p. 367) to postulate that the body image is best conceived as "a representation of attitudes and expectancy systems" related to the body and other persons. [See BODY IMAGE.]

Consistency in behavior is greatly enhanced through verbal interaction and conceptual classification, as research findings on the appearance of discriminatory responses by and toward American Negro children show so clearly (Clark & Clark 1947; Horowitz 1944). Very young children responded to skin-color differences but not preferentially. However, in a society systematically discriminating against Negroes, white and Negro children exhibited consistent preferences for light skin color by the age of 5.

While not every aspect of linguistic behavior is ego-involving, the child's instrumental mastery of language has general results that apply equally to the formation of categorical and attributive links between self and others (Lewis 1963). It liberates behavior from the total dictation of fluctuation in momentary bodily needs and the physical variations in external stimulation. From extensive research with children and cases of brain damage, Lurila concluded that "adoption of a verbal rule at once modifies the nature of all subsequent reactions . . . the stimulus in question becomes not a mere signal but an *item of general information*,

and all subsequent reactions depend more on the *system* it [stimulus] is taken into than on its physical properties" (1961, p. 44, italics in original).

The family and other adults in charge of the child's routine exert profound influence through their words and deeds on the nature and quality of the classificatory schemes defining what he is and is not. However, in line with G. H. Mead's theoretical scheme, the research of Piaget (1932) demonstrated that stability in the child's relatedness is attained slowly and, most decisively, in the company of other children. Little children behave consistently in dealings with others, according to rules or dictums handed down by authority figures, but easily lapse from them in the absence of authority. By participating in play with other children, the child has the greater opportunity to grasp notions of reciprocity with others and of mutual adherence to rules governing the give and take. [See DEVELOPMENTAL PSYCHOLOGY, article on A THEORY OF DEVELOPMENT.]

Thus, a series of experiments and "age-norm" studies (reviewed in Sherif & Sherif 1956) reveal that consistency in competing with others, in co-operating with others, in expressing sympathy at another's distress, in responsibility for self and others, and in setting goals for one's own performance appear gradually as the child participates in social and cooperative forms of play in contrast to earlier side-by-side or parallel play.

Slowly—and with confusion—the classificatory schemes defining self and others acquire longer dimensions in time and space. The immediate is located with reference to increasingly greater ranges of past and future (Lewis 1963). Geographical ranges of self-relatedness increase gradually from the perceptual scope of the child ("my house") to more distant and unseen, but conceptualized, places and the people in them.

The scope of time, place, and kind of persons included in categories for self and not-self varies enormously, along with their qualitative nature, according to prevailing social, cultural, material, and socioeconomic environments. The common property of self components in socialized members of all societies is the regulation of behavior within bounds of acceptability defined by the particular organizational and value systems of those groups with which the person identifies himself. Consistent evaluations of one class of objects (persons) and differential (sometimes invidious) evaluations of others is evidence of an ego component—an attitude relating self to that stimulus domain. The conception of self components (attitudes) as categorical schemes for evalua-

tion, including a latitude for acceptance and a latitude of rejection by the person, has led directly to operational procedures for assessing the person's ego involvement in various respects (Sherif, Sherif, & Nebergall 1965; Sherif, Sherif, & Kent 1967).

In addition, all known cultures present periods or stages in human development requiring alteration of the self concept as it is formed at the time. The years of transition from childhood to adulthood and the years of old age are two such periods. These particular transitions are marked by bodily changes that impel a change in self.

### Self and reference groups or sets

Research attempts failing to include explicit environmental factors have yielded inconclusive correlations between the person's self-ratings at two different points in time and subjectively circular accounts of self (Wylie 1961). In analyzing the "presentation of the self" in a variety of social situations, Goffman concluded that the person's characteristic consistency is a "collaborative manufacture" involving social arrangements and supporting performances by people within them (e.g., 1956, p. 253). Even advocates of a "phenomenal self" as determinant of all behavior could not ignore that much personal consistency and many changes in personal identity that occur with age or with taking on occupations and different social status are directly related to stabilities and changes in the social environment.

But individuals are differentially selective of their social environments, and modern social systems are extraordinarily complex and changing. A particular individual could develop within varying combinations of groups and institutions with differing values, rates of change, and stability. Owing to his advanced conceptual abilities, man may relate himself to persons and groups not present, spatially or temporally.

Therefore, unless the person is a fully integrated member of only one group and unless the social situation is fully structured as to socially desired outcomes, there is a need for concepts relating self to environmental events that may not be contemporaneous or spatially present. One such concept is that of reference groups or sets; these are defined as groups or classifications of people to whom the individual relates himself psychologically or to which he aspires to belong (Sherif & Sherif 1956; see the 1948 edition).

The concept of reference group, linking self components to environmental structures not necessarily present, is a distinctly human concept,

as the student of animal behavior J. P. Scott observed (1953, p. 69). It is unnecessary in studying subhuman behavior. It is probably unnecessary for analysis of self in an isolated, illiterate group. Only in differentiated societies is it possible that groups of actual membership may be anchors for self-identity.

From the research viewpoint, the concepts of self as a constellation of attitudes linked with identifiable reference groups and sets provide tools for integrating behavioral (individual) and sociocultural levels of analysis (Sherif 1962). A sharp dichotomy between individualistic and cultural (group) determination of behavior resists both argument and analysis but yields to research evidence that groups and populations have properties related to the development of self-other attitudes; self-other attitudes, in turn, display dimensional and classificatory features not necessarily identical with sociocultural prescriptions, but greatly clarified when related to them.

**Reference groups and self appraisal.** Asked to answer "Who am I?" the person's usual response is his name and social classifications, sometimes modified by adjectives placing him within the category (cf. Bugental & Zelen 1950; Kuhn & McPartland 1954). The social labels are typically exhausted before idiosyncratic responses appear.

The psychological import of this rather prosaic finding is vast: Each social category carries a complex of characteristics and positions within it that etch the specifics of a self image whether the individual actually belongs to that category or not. The bulk of the population of the United States, identifying themselves as "middle class," display a constellation of attitudes related to a middle-class position whether their individual socioeconomic levels warrant the designation or not (Centers 1947). Female college students who come from conservative families and, in time, take a liberal college student body as their reference group change their attitudes in diverse respects, not merely in identifying themselves with a particular college. However, those retaining a primary group reference, while classifying themselves as students, do not change at all (Newcomb 1950).

Groups, populations, and sets of people live in differing material and social environments that give focus to a complex of social values, setting bounds for the self-radius of persons who classify themselves as "belonging" within them. Thus, in the United States, the conceived range of achievement for self (from minimum to maximum) and the nature of personal goals varies systematically according to socioeconomic level and sociocultural

composition of reference sets; the range of achievement is most similar with respect to certain material possessions uniformly portrayed as success symbols in mass communication (Sherif & Sherif 1964). While upper-class youth are more likely to have high self-esteem than lower-class youth, the largest differences in self-esteem occur between groupings differentiated by both class and distinctive religious-ethnic cultures in the United States. Values cherished by youth in different socioeconomic and religious groupings differ, but there are marked similarities among them that indicate that they are all, nonetheless, members of the same society (Rosenberg 1965).

The reference-group concept permits specification of the particular group or set of people on whom the individual depends in appraising himself and others. In complex and changing societies, these people may not be readily identified by socioeconomic classification or geographical location. When the person locates himself within a set or group of people, the relative status of this group in the social organization and his own position within it serve as standards (anchors) for his appraisals of performance by himself and others.

In an experiment that served as a model for numerous others, Chapman and Volkmann (1939) showed that one's level of aspiration is anchored in the status of his own reference set relative to other reference sets. University students spontaneously raised or lowered their predictions for self when the group with whom they compared self was respectively "inferior" or "superior" to their own reference sets.

When anchored in the person's reference set, self-attitudes exert a stabilizing effect on performance. The relevant experiments have all used special instructions or varied tasks to assess the effects of ego involvement, and the findings hinge on the researcher's prior knowledge of values that are prized by the subjects' reference set (for example, for college students high intelligence, good university records, and contribution to science). The outcome of such experiments has been the repeated demonstration that such manipulations, arousing the person's mettle to prove his worth, result in greater consistency (less variation) of behavior in setting goals for performance, in self-confidence, in various personal characteristics, in learning, and in forgetting (see Allport 1943; M. Sherif & Cantril 1947). [See REFERENCE GROUPS.]

**Discrepant group membership.** While existence in an interacting group affects the individual's self concerns whether he takes stock of himself on their terms or not, attitudes relating self to others

are most predictable when the group is also the person's reference group. Siegel and Siegel (1957) found that over a period of time a person's attitudes coincided most with the values of groups that were also reference groups for him. A person who lived with a group whose values were at variance with his reference set was affected by it, but his attitudes resembled those of the reference set more closely.

Judgments of one's standing (rank) relative to others and of the rank assigned to self by others differ for those who are tied to the immediate group and those whose reference sets are outside of it. A study of small task groups in an isolated military base showed a general tendency to overestimate one's own rank and the rank that others would assign one. As a result, self-ranking and estimated ranking by others were more closely related than either were to actual ranks made by fellow members. However, those whose self-rankings disagreed most with the rank assigned them by others in the group were preponderantly married men with higher military rank and educational level. As a result, they were less tied to the reactions of the work group in rating themselves and tended to use standards from their other reference sets (Reeder, Donohue, & Biblarz 1962).

**Salience of different groups.** "I, who for the time have staked my all on being a psychologist, am mortified if others know much more psychology than I. But I am contented to wallow in the grossest ignorance of Greek. . . . Had I 'pretensions' to be a linguist, it would have been just the reverse" (James 1890, vol. 1, p. 310). The problem of self-reference-group relationship stated succinctly by James still holds the greatest promise for future research.

All components of the self are not equal in importance to the individual over time, and their relative importance varies in different situations. For every person, there is some order or hierarchy in the constellation of self values such that the ways, the time, and the relative frequency with which he becomes ego-involved differ systematically from person to person. Differences of this sort between individuals acquire some rational pattern when the hierarchy of their self-values is related to the relative importance of their various reference sets.

**Adolescence and marginality.** The period of adolescence in modern societies may serve as a prototype for study of the problem. During the prolonged and ill-defined transition from childhood to adulthood in Western industrialized societies, the adolescent is betwixt and between ref-

erence groups, much like a "marginal man." Lack of stable anchors for self arouses experiences of uncertainty and conflict. Grownups provide few ready-made paths for the transition that fully satisfy the adolescent's growing urges and his desire to prove himself adult. At this same time, he is provoked by the uncertainties of his standing. Scanning his environment for some stable anchor for self-identity, he turns increasingly toward age-mate groups and sets. Even though his parents be loved and valued, the result is reduced emphasis on parental capability and overestimation of the worth of age-mate capacities, as Prado (1958) has shown experimentally.

Absorption of self-identity within the organizational pattern and values developed in age-mate groups varies with the availability and stability of other reference ties (family, school, community, etc.); however, the adolescent's hierarchy of ego attitudes is closely linked to the values of his informal groups. When these values conflict with adult prescriptions, the defiance of adult standards, including legal violations, is self-justified by measuring oneself relative to the values of the youth group [Sherif & Sherif 1964; *see also* ADOLESCENCE].

**Multiple group membership.** Like many adults in multifaceted, complex societies, the adolescent belongs to multiple groups whose values may conflict. The member of multiple groups with contradictory values frequently faces situations of choice in abiding by the values of one reference set at the expense of the other. Still more painfully, he or she may form ego attitudes relative to different reference groups whose simultaneous arousal is bound to produce psychological conflict, uncertainty, and confused search for resolution. Such, for example, is the plight of many women today who conceive of themselves simultaneously as women and mothers in traditional terms and as modern, independent women on a par with men (Seward 1946).

Choice situations provide one index of the salience of the individual's self-attitudes. For example, during the crisis over desegregation in Little Rock, Arkansas, ministers faced the choice of speaking out against violence, as ministers of brotherly love, or of remaining silent in keeping with the standards of their segregationist congregations. Only a few of them chose to speak out in congruence with their ministerial self-identity (Campbell & Pettigrew 1959).

**Stability and change of ego attitudes.** Numerous instances of change in ego attitudes have been mentioned in this article. Stability may be at-

tributed in large part to the regularity and continuity of the person's social setting. Yet resistance to change inheres in their formation and functioning as well. Changing attitudes that form part of the person's relatedness to other persons, groups, and values amounts to changing part of the self-identity, which is the epicenter of experienced personal stability, even though it may not be an integrated harmonious structure. Disturbance of self-attitudes once they are formed is psychologically uncomfortable and even painful.

Resistance to change increases in proportion to the degree of personal commitment on the matter in question. When a person is highly involved in the matter in question, he is less likely to change his attitude readily and, when he does, is likely to change less than persons to whom the attitude is of moderate importance. In matters of high ego involvement, the individual is very discriminating in accepting proposals that differ even slightly from the values he has come to cherish as defining the attributes of himself and other persons who count in his eyes; he is prone to reject all those seen as different. Thus, his categorization of ego-involving material reveals broad latitudes of rejection in comparison with the narrow, but cherished, range of acceptance. Attempts to persuade him otherwise are likely to fail within the range that he has already rejected categorically as unlike himself and, therefore, to exert no lasting effects other than, perhaps, to reaffirm the correctness of his self conception. On matters of less consequence, he is more amenable to change and innovation, because he has not committed himself against such a broad range of discrepant values (Sherif, Sherif, & Nebergall 1965; Sherif, Sherif, & Kent 1967).

By studying the relative importance of a person's reference groups, their values, and his position within them, the degrees of a person's ego involvement in various respects may eventually become more amenable to research.
